1 Riemann integration

Aims:

1. Rigorise $\int_a^b f(x) \, dx$
2. learn how to compute integrals

Prehistoric way:

$$\int_0^1 f(x) \, dx = \sum_{j=0}^{n-1} f\left(\frac{j}{n}\right) \frac{1}{n}.$$

$$\sum_{j=0}^n j^2 = x \frac{\partial}{\partial x} x \frac{\partial}{\partial x} \sum_{j=0}^n x^j \Big|_{x=1} = x \frac{\partial}{\partial x} x \frac{\partial}{\partial x} \frac{x^{n+1} - 1}{x - 1} \Big|_{x=1}$$

$$= \frac{1}{n^3} \sum_{j=0}^{n-1} j^2 = \frac{1}{n^3} \frac{n(n - \frac{1}{2})(n - 1)}{3} \rightarrow \frac{1}{3}.$$

Remark. 1. Does the answer depend on where do we compute f ?
 2. FTC is here less important than a consistent definition

1.1 Definition of Riemann integrals

Definition 1.1.1. 2 intervals $I_1, I_2 \subset \mathbb{R}$ are *almost disjoint* if $I_1 \cap I_2$ is \emptyset or one single point.

Definition 1.1.2. A *partition* P of a closed interval $I \subset \mathbb{R}$ is a set $\{I_1, \dots, I_n\}$ of closed almost disjoint intervals such that $\bigcup_{i=1}^n I_i = I$.

Let $f : [a, b] \rightarrow \mathbb{R}$.

Notation. $M = \sup f$, $m = \inf f$, $M_k = \sup_{I_k} f$, $m_k = \inf_{I_k} f$

Definition 1.1.3. The *upper Riemann sum* of f with respect to P is

$$U(f, P) = \sum_{k=1}^n M_k |I_k|.$$

Lower Riemann sum is

$$L(f, P) = \sum_{k=1}^n m_k |I_k|.$$

Clearly

$$\begin{aligned} m &\leq m_k \leq M_k \leq M \\ \Rightarrow m|I_k| &\leq m_k|I_k| \leq M_k|I_k| \leq M|I_k| \\ \Rightarrow m(b-a) &\leq L(f, P) \leq U(f, P) \leq M(b-a). \end{aligned}$$

Notation. $\mathcal{B}[a, b]$ denotes the set of all bounded functions on $[a, b]$.

Let \mathcal{P} be the set of all partition P 's, then the sets $\{L(f, P)\}_{P \in \mathcal{P}}$, $\{U(f, P)\}_{P \in \mathcal{P}}$ are bounded.

Definition 1.1.4. *Upper Riemann integral* of f is defined

$$U(f) = \inf_{P \in \mathcal{P}} U(f, P), \quad [\text{least overestimator}]$$

and *lower Riemann integral*

$$L(f) = \sup_{P \in \mathcal{P}} L(f, P), \quad [\text{greatest underestimator}].$$

Definition 1.1.5. $f \in \mathcal{B}[a, b]$ is *Riemann integrable* if $U(f) = L(f)$, in which case we write

$$\int_a^b f(x) = L(f) = U(f).$$

Remark. 1. By default interval is bounded

2. By definition unbounded function are not Riemann integrable

3. We consider integrals over unbounded intervals and/or unbounded functions as “improper”

4. Shorthand:

- $\int_a^b f(x) \, dx \mapsto \int_a^b f$
- integrable \equiv Riemann integrable

Example 1.1.6. 1. For

$$f(x) = \begin{cases} 1 & x > 0 \\ 0 & x = 0 \end{cases},$$

we have $U(f, P) = 1$ and $L(f, P) = 1 - |I_1|$ since the first interval always contain 0. Clearly we then have $U(f) = 1$. We also have $L(f) = 1$ since 1 is an upper bound and $\forall \varepsilon > 0, \exists P : 1 - \varepsilon < L(f, P)$. Therefore $\int_0^1 f = 1$.

2. Let

$$f(x) = \begin{cases} 1 & x \in \mathbb{Q} \\ 0 & x \notin \mathbb{Q} \end{cases},$$

then any $I \subset \mathbb{R}$ contains both rationals and irrationals [completeness of \mathbb{R}] $\Rightarrow \forall P, L(f, P) = 0, U(f, P) = 1 \Rightarrow L(f) = 0, U(f) = 1$, therefore f not integrable.

By definition integrable functions are boring. Next step: build classes of integrable function.

Definition 1.1.7. The partition $Q = \{I_1, \dots, I_n\}$ of $[a, b]$ is a *refinement* of $P = \{J_1, \dots, J_k\}$ if $\forall k, J_k$ is union of one or more I_k 's (or the set of end points of P is a subset of that of Q).

Theorem 1.1.8. $f \in \mathcal{B}[a, b]$, $P, Q \in \mathcal{P}$. If Q is a refinement of P , then

$$L(f, P) \leq L(f, Q) \leq U(f, Q) \leq U(f, P).$$

Proof. Let $P = \{I_1, I_2, \dots, I_n\}, Q = \{J_1, J_2, \dots, J_l\}, m_k = \inf_{I_k} f, M_k = \sup_{I_k} f, \overline{m}_j = \inf_{J_j} f, \overline{M}_j = \sup_{J_j} f$. Since

$$\forall k, \exists \alpha_k \leq \beta_k : I_k = \bigcup_{j=\alpha_k}^{\beta_k} J_j,$$

we have $m_k \leq \overline{m_j}$, $M_k \geq \overline{M_j}$ and

$$\begin{aligned} L(f, P) &= \sum_{k=1}^n m_k |I_k| = \sum_{k=1}^n m_k \sum_{j=\alpha_k}^{\beta_k} |J_j| \\ &= \sum_{k=1}^n \sum_{j=\alpha_k}^{\beta_k} m_k |J_j| \leq \sum_{k=1}^n \sum_{j=\alpha_k}^{\beta_k} \overline{m_j} |J_j| = \sum_{j=1}^l \overline{m_j} |J_j| = L(f, Q). \end{aligned}$$

Similarly we can prove $U(f, Q) \leq I(f, P)$. □

Theorem 1.1.9. $f \in \mathcal{B}[a, b]$. If P, Q are any two partitions, then $L(f, P) \leq U(f, Q)$.

Proof. Let R be a refinement of P, Q [$R = P \cup Q$]. From Theorem 1.1.8,

$$L(f, P) \leq L(f, R) \leq U(f, R) \leq U(f, Q).$$

□

Corollary 1.1.10. If $f \in \mathcal{B}[a, b]$, then $L(f) \leq U(f)$.

Proof. We have $\forall P, Q \in \mathcal{P}$, $L(f, P) \leq U(f, Q)$, in other words $L(f, P)$ is a lower bound for $\{U(f, Q)\}$. Then $L(f) \leq L(f, P) \leq \inf_{Q \in \mathcal{P}} U(f, Q) = U(f)$. □

Theorem 1.1.11. $f \in \mathcal{B}[a, b]$ is integrable if and only if $\forall \varepsilon > 0, \exists P : U(f, P) - L(f, P) < \varepsilon$.

Proof. \Rightarrow : Let $P_1, P_2 \in \mathcal{P}$ satisfy

$$\begin{cases} U(f, P_1) < U(f) + \frac{\varepsilon}{2} \\ L(f, P_2) > L(f) - \frac{\varepsilon}{2} \end{cases}$$

and P a refinement of P_1, P_2 . Then

$$\left. \begin{aligned} U(f, P) &\leq U(f, P_1) < U(f) + \frac{\varepsilon}{2} \\ L(f, P) &\geq L(f, P_2) > L(f) - \frac{\varepsilon}{2} \end{aligned} \right\} \Rightarrow L(f) - \frac{\varepsilon}{2} < L(f, P) \leq U(f, P) < U(f) + \frac{\varepsilon}{2}.$$

Since f is integrable, $L(f) = U(f)$, so $U(f, P) - L(f, P) < \varepsilon$.

\Leftarrow : $\forall P \in \mathcal{P}$ we have $U(f) \leq U(f, P)$ and $L(f) \geq L(f, P)$, so

$$\forall \varepsilon > 0, \exists P : 0 \leq U(f) - L(f) \leq U(f, P) - L(f, P) < \varepsilon \Rightarrow U(f) = L(f).$$

□

Theorem 1.1.12. $f \in \mathcal{B}[a, b]$ is integrable iff $\exists (P_n)_{n \geq 1} \subset \mathcal{P}$ such that

$$\lim_{n \rightarrow \infty} (U(f, P_n) - L(f, P_n)) = 0.$$

Handwavy proof. Set $\varepsilon = \frac{1}{n}$ and use Theorem 1.1.11. □

Definition 1.1.13. $f : \Omega \rightarrow \mathbb{R}$ is *uniformly continuous* if

$$\forall \varepsilon > 0, \exists \delta(\varepsilon) : (x, y \in \Omega, |x - y| < \delta(\varepsilon)) \Rightarrow |f(x) - f(y)| < \varepsilon.$$

Theorem 1.1.14 (Continuity and uniform continuity coincide on closed bounded intervals). Let $f \in \mathcal{C}[a, b]$, then f is uniformly continuous.

Proof. (by contradiction) Suppose f is not uniformly continuous, then $\exists \varepsilon > 0 : \forall \delta > 0, \exists x, y \in [a, b]$ such that $|x - y| < \delta \Rightarrow |f(x) - f(y)| \geq \varepsilon$. Take $\delta_n = \frac{1}{n}$ and $(x_n), (y_n) \subset [a, b]$ such that $|x_n - y_n| \leq \frac{1}{n} \rightarrow 0$. Since $[a, b]$ is bounded, by Bolzano-Weierstrass we can find subsequences $(x_{n_k}), (y_{n_k})$ that converge to $x = y \in [a, b]$ as $[a, b]$ is closed and $\lim_{k \rightarrow \infty} y_{n_k} = \lim_{k \rightarrow \infty} x_{n_k} + \underbrace{(y_{n_k} - x_{n_k})}_0$. But $|f(x_{n_k}) - f(y_{n_k})| \geq \varepsilon \forall k \Rightarrow \lim_{k \rightarrow \infty} |f(x_{n_k}) - f(y_{n_k})| \geq \varepsilon$ and by continuity of composition $|f(x) - f(x)| \geq \varepsilon$, a contradiction. \square

Remark. Generally continuity \nRightarrow uniform continuity, i.e. latter is stronger, e.g. $x \mapsto e^x$ on \mathbb{R} (closed but unbounded) and $x \mapsto \frac{1}{x}$ on $(0, 1)$ (bounded but not closed) are continuous but not uniformly. [We also have Lipschitz continuity which is even stronger (remember the double cone?).] Anyway we are now ready to prove the following important theorem.

Theorem 1.1.15 (*). Let $f : [a, b] \rightarrow \mathbb{R}$ be continuous. Then f is integrable.

Proof. It follows that f is uniformly continuous, i.e.

$$\forall \varepsilon > 0, \exists \delta : (x, y \in [a, b], |x - y| < \delta) \Rightarrow |f(x) - f(y)| < \frac{\varepsilon}{b - a}.$$

Let $P = \{I_1, \dots, I_n\}$ be a partition of $[a, b]$ such that $|I_k| < \delta$. I_k is closed bounded $\Rightarrow \exists x_k, y_k \in I_k : M_k = \sup_{I_k} f = f(x_k), m_k = \inf_{I_k} f = f(y_k)$ [attainment of bounds] and $|I_k| < \delta$, so $\forall k, |x_k - y_k| < \delta \Rightarrow M_k - m_k < \frac{\varepsilon}{b - a}$. Then

$$U(f, P) - L(f, P) = \sum_{k=1}^n (M_k - m_k) |I_k| \leq \sum_{k=1}^n \frac{\varepsilon}{b - a} |I_k| = \frac{\varepsilon}{b - a} (b - a) = \varepsilon \quad \forall \varepsilon > 0,$$

hence by Theorem 1.1.11 f is integrable. \square

Theorem 1.1.16. $f : [a, b] \rightarrow \mathbb{R}$ is monotonic. Then f is integrable. [It doesn't have to be continuous!]

Proof. Let P be a uniform partition of $[a, b]$ into n subintervals:

$$I_k = \left[a + \frac{b - a}{n}(k - 1), a + \frac{b - a}{n}k \right], \quad 1 \leq k \leq n.$$

WLOG, let f be increasing. Then

$$\begin{aligned} U(f, P) - L(f, P) &= \sum_{k=1}^n \left(\sup_{I_k} f - \inf_{I_k} f \right) \frac{b - a}{n} \\ &= \frac{b - a}{n} \sum_{k=1}^n \underbrace{f \left(a + \frac{b - a}{n}k \right) - f \left(a + \frac{b - a}{n}(k - 1) \right)}_{\text{telescopic}} \\ &= \frac{b - a}{n} (f(b) - f(a)) \rightarrow 0. \end{aligned}$$

Therefore by Theorem 1.1.11 f is integrable. □

Now we can integrate functions that cannot be visualized.

Example 1.1.17. Let $(\gamma_k)_{k \geq 1}$ be any enumeration of $\mathbb{Q} \cap [0, 1]$. Define $f : [0, 1] \rightarrow \mathbb{R}$:

$$f(x) = \begin{cases} 0 & x = 0 \\ \sum_{k: r_k \leq x} \frac{1}{2^k} & x > 0 \end{cases}$$

It's well-defined as $\sum_{k \geq 1} \frac{1}{2^k} < \infty$. Also f is increasing. Choose any $\delta > 0$,

$$f(x + \delta) - f(x) = \sum_{k: \begin{cases} r_k < x + \delta \\ r_k \geq x \end{cases}} \frac{1}{2^k} \geq 0.$$

Hence f is integrable by Theorem 1.1.16.

1.2 Properties of Riemann integral

Theorem 1.2.1 (Linearity of integration). Let $f, g : [a, b] \rightarrow \mathbb{R}$ be integrable. Let $c \in \mathbb{R}$. Then

1. cf is integrable and $\int_a^b cf = c \int_a^b f$;
2. $f + g$ is integrable and $\int_a^b (f + g) = \int_a^b f + \int_a^b g$.

Remark. If f, g are integrable then $\alpha f + \beta g$ is integrable and $\int_a^b (\alpha f + \beta g) = \alpha \int_a^b f + \beta \int_a^b g$, an immediate result and equivalent form of the theorem.

Proof. 1. Assume $c \geq 0$ ($c < 0$ - an exercise). Take any $P = \{I_1, \dots, I_n\}$. We have

$$\begin{cases} \sup_{I_k} cf = c \sup_{I_k} f \\ \inf_{I_k} cf = c \inf_{I_k} f \end{cases} \Rightarrow \begin{cases} U(cf, P) = cU(f, P) \\ L(cf, P) = cL(f, P) \end{cases}$$

Then $U(cf) = \inf_{P \in \mathcal{P}} U(cf, P) = c \inf_{P \in \mathcal{P}} U(f, P) = cU(f)$. Similarly $L(cf) = cL(f)$, so $U(cf) = L(cf) = cU(f) = c \int_a^b f$.

2. $U(f + g, P) = \sum_{k=1}^n \underbrace{\sup_{I_k} (f + g)}_{\leq \sup_{I_k} f + \sup_{I_k} g} |I_k| \leq U(f, P) + U(g, P)$. Exactness of $\inf \Rightarrow \forall \varepsilon > 0$

$\exists P_1, P_2 \in \mathcal{P}$ such that

$$\begin{cases} U(f, P_1) < U(f) + \frac{\varepsilon}{2} \\ U(g, P_2) < U(g) + \frac{\varepsilon}{2} \end{cases}.$$

Let Q be a refinement of P_1, P_2 , then

$$U(f + g) \leq U(f, Q) + U(g, Q) \leq U(f, P_1) + U(g, P_2) \leq U(f) + U(g) + \varepsilon.$$

Similarly $L(f + g) \geq L(f) + L(g) - \varepsilon$. Since f, g are integrable, $L(f) = U(f)$, $L(g) = U(g)$, so

$$\int_a^b f + \int_a^b g - \varepsilon \leq L(f + g) \leq U(f + g) \leq \int_a^b f + \int_a^b g + \varepsilon,$$

and since ε is arbitrary, we conclude that

$$L(f + g) = U(f + g) = \int_a^b (f + g) = \int_a^b f + \int_a^b g.$$

□

Theorem 1.2.2 (Monotonicity of integration). $f, g : [a, b] \rightarrow \mathbb{R}$ are integrable. If $f \leq g$ then $\int_a^b f \leq \int_a^b g$.

Proof. $g \geq f \Rightarrow g - f \geq 0 \Rightarrow \forall P \in \mathcal{P}, U(g - f, P) \geq 0 \Rightarrow U(g - f) \geq 0$. But $g - f$ is integrable by previous theorem, so

$$\int_a^b (g - f) = \int_a^b g - \int_a^b f = U(g - f) \geq 0.$$

□

Corollary 1.2.3. $f : [a, b] \rightarrow \mathbb{R}$ is integrable. Then

$$\inf_{[a,b]} f \cdot (b - a) \leq \int_a^b f \leq \sup_{[a,b]} f \cdot (b - a).$$

Corollary 1.2.4 (Integral form of Mean Value Theorem). $f \in \mathcal{C}[a, b]$. Then $\exists c \in [a, b]$ such that

$$f(c) = \underbrace{\frac{1}{b - a} \int_a^b f}_{\text{the average value of } f \text{ on } [a, b]}.$$

Proof. Since f is continuous, it attains both inf and sup, hence

$$\exists x, y : f(x) = m, f(y) = M,$$

therefore by IVT f attains every value in $[m, M]$, and by previous corollary,

$$m \leq \frac{1}{b - a} \int_a^b f \leq M.$$

□

Theorem 1.2.5. $f : [a, b] \rightarrow \mathbb{R}$ is integrable. Then $|f|$ is also integrable and

$$\left| \int_a^b f \right| \leq \int_a^b |f|.$$

Hint for proof. First prove $\sup |f| - \inf |f| \leq \sup f - \inf f$. Then integrability follows from Theorem 1.1.11. The inequality follows from $-|f| \leq f \leq |f|$ and the monotonicity. □

Theorem 1.2.6 (Additivity). $f : [a, b] \rightarrow \mathbb{R}$, $c \in (a, b)$. f is integrable on $[a, b] \Leftrightarrow f$ is integrable on $[a, c]$, $[c, b]$, and

$$\int_a^b f = \int_a^c f + \int_c^b f.$$

Proof. \Rightarrow : f is integrable on $[a, b] \Rightarrow \forall \varepsilon > 0, \exists P \in \mathcal{P} : U(f, P) - L(f, P) < \varepsilon$. Let P_c be $P \cup \{c\}$ (in terms of endpoints), $Q = P|_{[a, c]}$ (a partition of $[a, c]$) and $R = P|_{[c, b]}$ (a partition of $[c, b]$):

By definition it's clear that

$$\begin{aligned} U(f, P_c) &= U(f, Q) + U(f, R) \\ L(f, P_c) &= L(f, Q) + L(f, R). \end{aligned} \quad (*)$$

Hence

$$\underbrace{U(f, P_c) - L(f, P_c)}_{< \varepsilon} = \underbrace{U(f, Q) - L(f, Q)}_{\geq 0} + \underbrace{U(f, R) - L(f, R)}_{\geq 0},$$

therefore

$$U(f, Q) - L(f, Q), \quad U(f, R) - L(f, R) < \varepsilon,$$

giving us $f|_{[a, c]}$ and $f|_{[c, b]}$ are integrable.

\Leftarrow : We have that $f|_{[a, c]}$ and $f|_{[c, b]}$ are integrable. Then

$$\forall \varepsilon > 0, \exists Q, R : \begin{cases} U(f, Q) - L(f, Q) < \frac{\varepsilon}{2} \\ U(f, R) - L(f, R) < \frac{\varepsilon}{2} \end{cases} \quad (**)$$

where Q, R are partitions of $[a, c]$, $[c, b]$ respectively. Consider $P_c = Q \cup R$ (endpoints) and use $(*)$ and $(**)$ to conclude.

We now establish additivity. We have

$$\int_a^b f \leq U(f, P_c) = U(f, Q) + U(f, R) \leq L(f, Q) + L(f, R) + \varepsilon \leq \int_a^c f + \int_c^b f + \varepsilon$$

and similarly

$$\int_a^b f \geq \int_a^c f + \int_c^b f - \varepsilon.$$

Since ε is arbitrary, we conclude that

$$\int_a^b f = \int_a^c f + \int_c^b f.$$

□

Theorem 1.2.7. $f : [a, b] \rightarrow \mathbb{R}$ is integrable. $\varphi : \mathbb{R} \rightarrow \mathbb{R}$ is continuous. Then $\varphi \circ f : [a, b] \rightarrow \mathbb{R}$ is integrable.

Proof. f is integrable \Rightarrow bounded, i.e. $\exists M > 0 : |f| \leq M$. So it's enough to consider φ on closed bounded interval $[-M, M]$ which is continuous, meaning φ is bounded, i.e. $\exists K > 0 : |\varphi| \leq K$ and φ is uniformly continuous, which means

$$\forall \bar{\varepsilon} > 0, \exists \delta_{\bar{\varepsilon}} > 0 : (x, y \in [-M, M], |x - y| < \delta_{\bar{\varepsilon}}) \Rightarrow |\varphi(x) - \varphi(y)| < \bar{\varepsilon}. \quad (*)$$

Also, f is integrable, meaning

$$\forall \eta > 0, \exists Q_{\eta} \in \mathcal{P} = \{I_1, \dots, I_n\} : U(f, Q_{\eta}) - L(f, Q_{\eta}) < \eta. \quad (**)$$

We want to show that

$$\forall \varepsilon > 0, \exists P \in \mathcal{P} : U(\varphi \circ f, P) - L(\varphi \circ f, P) < \varepsilon.$$

Take $P = Q_{\eta}$. Then

$$U(\varphi \circ f, Q_{\eta}) - L(\varphi \circ f, Q_{\eta}) = \sum_{k=1}^n \left(\underbrace{\sup_{I_k} \varphi \circ f - \inf_{I_k} \varphi \circ f}_{:= \text{osc}_{I_k} \varphi \circ f} \right) |I_k|.$$

The strategy is to break the sum into two parts: for the first sum we look at k 's such that $\sup_{I_k} \varphi \circ f - \inf_{I_k} \varphi \circ f < \delta_{\bar{\varepsilon}}$ which gives $\sup_{I_k} \varphi \circ f - \inf_{I_k} \varphi \circ f < \bar{\varepsilon}$ by uniform continuity of φ . For the second sum we look at k 's such that $\sup_{I_k} \varphi \circ f - \inf_{I_k} \varphi \circ f \geq \delta_{\bar{\varepsilon}}$, which there aren't many by $(**)$ and bounded by η :

$$\begin{aligned} \sum_{\substack{k: \text{osc}_{I_k} \varphi \circ f < \delta_{\bar{\varepsilon}}}} \text{osc}_{I_k} \varphi \circ f |I_k| + \sum_{\substack{k: \text{osc}_{I_k} \varphi \circ f \geq \delta_{\bar{\varepsilon}}}} \text{osc}_{I_k} \varphi \circ f |I_k| &\leq \bar{\varepsilon} \sum_{k=1}^n |I_k| + 2K \sum_{\substack{k: \text{osc}_{I_k} \varphi \circ f \geq \delta_{\bar{\varepsilon}}}} |I_k| \\ &= \bar{\varepsilon}(b-a) + \frac{2K}{\delta_{\bar{\varepsilon}}} \sum_{\substack{k: \text{osc}_{I_k} \varphi \circ f \geq \delta_{\bar{\varepsilon}}}} \delta_{\bar{\varepsilon}} |I_k| \\ &\leq \bar{\varepsilon}(b-a) + \frac{2K}{\delta_{\bar{\varepsilon}}} \sum_{\substack{k: \text{osc}_{I_k} \varphi \circ f \geq \delta_{\bar{\varepsilon}}}} \text{osc}_{I_k} \varphi \circ f |I_k| \\ &= \bar{\varepsilon}(b-a) + \frac{2K}{\delta_{\bar{\varepsilon}}} (U(f, Q_{\eta}) - L(f, Q_{\eta})) \\ &< \bar{\varepsilon}(b-a) + \frac{2K\eta}{\delta_{\bar{\varepsilon}}} \end{aligned}$$

where $\bar{\varepsilon}, \eta$ are arbitrarily positively small. Choose $\bar{\varepsilon} = \frac{\varepsilon}{2(b-a)}$, $\eta = \frac{\delta_{\bar{\varepsilon}}}{2K} \frac{\varepsilon}{2}$, then the above $= \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon$. \square

Remark. 1. A composition of two integrable functions is not necessarily integrable.

Example 1.2.8. Given $\varphi : \mathbb{R} \rightarrow \mathbb{R}$ and $f : [0, 1] \rightarrow \mathbb{R}$ defined as follow,

$$\varphi(x) = \begin{cases} 1 & x \neq 0 \\ 0 & x = 0 \end{cases}, \quad f(x) = \begin{cases} \frac{1}{q} & x = \frac{p}{q}, p, q \in \mathbb{N} \text{ coprime} \\ 0 & x = 0 \\ 0 & \text{otherwise} \end{cases}$$

then

$$\varphi \circ f(x) = \begin{cases} 1 & x \in \mathbb{Q} \cap (0, 1] \\ 0 & \text{otherwise} \end{cases}$$

which is not integrable.

2. What about $f \circ \varphi$ where f is integrable and φ continuous? Also not necessarily integrable. Counterexamples for this case are a bit harder to find.

Theorem 1.2.9. $f, g : [a, b] \rightarrow \mathbb{R}$ integrable, then $f \cdot g$ is integrable. Moreover, if g^{-1} is bounded, then g^{-1} is integrable.

Proof. f is integrable means f^2 is also, since $\forall x \in [a, b]$, $f^2(x) = \varphi(f(x))$ where $\varphi : y \mapsto y^2$ on \mathbb{R} which is continuous. We now write

$$f \cdot g = \frac{1}{4} ((f + g)^2 - (f - g)^2)$$

and by linearity of integration, $f \cdot g$ is integrable. If g^{-1} is bounded, then $\exists \varepsilon > 0 : |g(x)| \geq \varepsilon \forall x \in [a, b]$, and let

$$\varphi(y) = \begin{cases} \frac{1}{y} & |y| \geq \varepsilon \\ \frac{y}{\varepsilon^2} & |y| < \varepsilon \end{cases}$$

Then $\forall x \in [a, b]$, $\varphi(g(x)) = \frac{1}{g(x)}$ where g is integrable and φ continuous, therefore g^{-1} is integrable. \square

1.3 Fundamental theorem of calculus

i.e. how to compute $\int_a^b f$?

Theorem 1.3.1 (FTC). $f : [a, b] \rightarrow \mathbb{R}$ integrable, $F : [a, b] \rightarrow \mathbb{R}$ continuous and differentiable on (a, b) such that $F' = f$. Then

$$\int_a^b f(x) \, dx = F(b) - F(a).$$

Also called Newton-Leibniz formula.

Proof. It is enough to show that

$$\forall P \in \mathcal{P}, L(f, P) \leq F(b) - F(a) \leq U(f, P) \quad (*)$$

since taking the sup and inf of L and U the equality still holds, which is now $L(f) \leq F(b) - F(a) \leq U(f)$, and since f integrable, $L(f) = U(f)$ and therefore we have what we want to prove. So now let's prove $(*)$.

Let $P = \{I_1, \dots, I_k\}$ where $I_k = [x_{k-1}, x_k]$, $1 \leq k \leq n$. Note that $\forall k, \forall c_k \in I_k, \inf_{I_k} f \leq f(c_k) \leq \sup_{I_k} f$, and since F is continuous on $[x_{k-1}, x_k]$ and differentiable on (x_{k-1}, x_k) , by MVT

$$\exists c_k \in (x_{k-1}, x_k) : F(x_k) - F(x_{k-1}) = F'(c_k) \cdot (x_k - x_{k-1}) = f(c_k) \cdot (x_k - x_{k-1})$$

and therefore

$$\inf_{I_k} f |I_k| \leq F(x_k) - F(x_{k-1}) \leq \sup_{I_k} f |I_k|$$

and summing over all k 's gives us

$$L(f, P) \leq \underbrace{\sum_k F(x_k) - F(x_{k-1})}_{\text{telescopic}} \leq U(f, P)$$

and $(*)$ follows immediately. \square

Remark. $f : [a, b] \rightarrow \mathbb{R}$ is integrable \Rightarrow bounded. So FTC cannot be applied (yet) to unbounded functions, e.g.

$$\int_0^1 \frac{1}{2\sqrt{x}} \, dx = \sqrt{x} \Big|_0^1 = 1.$$

Remark (Conventional generalisation). If $b < a$,

$$\int_a^b f := - \int_b^a f$$

and

$$\int_a^a f = 0,$$

which is consistent with additivity.

Theorem 1.3.2. Let $f : [a, b] \rightarrow \mathbb{R}$ be integrable, define $F : [a, b] \rightarrow \mathbb{R}, x \mapsto \int_a^x f$. Then $F \in \mathcal{C}[a, b]$. Moreover, if $x \in (a, b)$ and f is continuous at x , $F'(x) = f(x)$.

Proof. Let $x \in (a, b)$. $\forall h \in \mathbb{R}$ sufficiently small that $x + h \in [a, b]$, $F(x + h) - F(x) = \int_a^{x+h} f - \int_a^x f = \int_x^{x+h} f$ by additivity. f is integrable implies that $\exists M > 0 : |f| \leq M$. Then

$$|F(x + h) - F(x)| = \left| \int_x^{x+h} f \right| \leq \int_x^{x+|h|} |f| \leq M \int_x^{x+|h|} 1 = M|h|,$$

i.e. F is Lipschitz continuous, hence continuous. Checking left and right continuity at $x = b, a$ is left as an exercise. We now want to show that

$$\lim_{h \rightarrow 0} \frac{F(x + h) - F(x)}{h} = f(x),$$

i.e.

$$\lim_{h \rightarrow 0} \left(\frac{1}{h} \int_x^{x+h} f(t) \, dt - \underbrace{\frac{f(x)}{\frac{1}{h} \int_x^{x+h} f(x) \, dt}}_{\frac{f(x)}{f(x)}} \right) = 0.$$

But f is continuous at x , i.e. $\forall \varepsilon > 0, \exists \delta > 0 : |x - y| < \delta \Rightarrow |f(x) - f(y)| < \varepsilon$. Take $h : |h| < \delta$. Then

$$\left| \frac{1}{h} \int_x^{x+h} (f(t) - f(x)) \, dt \right| \leq \frac{1}{|h|} \int_x^{x+|h|} \underbrace{|f(t) - f(x)|}_{< \varepsilon \text{ as } |t-x| \leq |h| < \delta} \, dt < \frac{1}{|h|} \varepsilon |h| = \varepsilon.$$

Hence the desired result. \square

Theorem 1.3.3. Let $f : [a, b] \rightarrow \mathbb{R}$ be integrable. If f is right-continuous at a ,

$$\lim_{h \rightarrow 0+} \frac{1}{h} \int_a^{a+h} f = f(a).$$

Similarly, if f left-continuous at b ,

$$\lim_{h \rightarrow 0+} \frac{1}{h} \int_{b-h}^b f = f(b).$$

Proof. f is right-continuous at a means $\forall \varepsilon > 0, \exists \delta > 0 : 0 < t - a < \delta \Rightarrow |f(t) - f(a)| < \varepsilon$. Let $h : |h| < \delta$. Then

$$\begin{aligned} \left| \frac{1}{h} \int_a^{a+h} f - f(a) \right| &= \left| \frac{1}{h} \int_a^{a+h} f(t) \, dt - \frac{1}{h} \int_a^{a+h} f(a) \, dt \right| \\ &\leq \frac{1}{|h|} \int_a^{a+|h|} |f(t) - f(a)| \, dt \\ &< \frac{1}{|h|} \varepsilon |h| = \varepsilon. \end{aligned}$$

The proof is similar for the second part. \square

Remark. Theorem 1.3.2 and 1.3.3 together mean that f is differentiable at any $x \in [a, b] : f$ is continuous at x .

The definition of $\int_a^b f \, \forall a, b \in \mathbb{R}$ allowed us to avoid looking at 1-sided limits for $x \in (a, b)$.

Example 1.3.4. Now we know $\forall p \geq 0$,

$$\int_0^1 x^p = \int_0^1 \left(\frac{x^{p+1}}{p+1} \right) = \frac{x^{p+1}}{p+1} \Big|_0^1 = \frac{1}{p+1},$$

which is hard to do by hand.

1.4 Methods of integration

Theorem 1.4.1 (Integration by parts). $f, g : [a, b] \rightarrow \mathbb{R}$ are continuous, differentiable on (a, b) such that f', g' are integrable. Then

$$\int_a^b f g' = f(b)g(b) - f(a)g(a) - \int_a^b f' g.$$

Proof. $f g', f' g$ and $(f g)' = f' g + f g'$ are all integrable as sums of products of integrable functions by Theorem 1.2.7. Then

$$\begin{aligned} \int_a^b (f g)' &= f(b)g(b) - f(a)g(a) && \text{by FTC} \\ &= \int_a^b (f' g + f g') && \text{by product rule} \\ &= \int_a^b f' g + \int_a^b f g' && \text{by linearity.} \end{aligned}$$

Rearranging gives desired result. □

Example 1.4.2. For any $a, b > 0$,

$$\begin{aligned} \int_a^b \log(x) \, dx &= \int_a^b \log(x) \cdot x' \, dx = \log(b)b - \log(a)a - \int_a^b \frac{1}{x} x \, dx \\ &= \log(b)b - \log(a)a - (b - a). \end{aligned}$$

Theorem 1.4.3 (Change of variables). $f : [a, b] \rightarrow \mathbb{R}$ is differentiable such that $f' : [a, b] \rightarrow \mathbb{R}$ is integrable, g is continuous on image $f([a, b])$. Then

$$\int_a^b g(f(x)) f'(x) \, dx = \int_{f(a)}^{f(b)} g(t) \, dt.$$

This is true even if $f(b) < f(a)$.

Proof. For $x \in f([a, b])$, define

$$G(x) = \int_{f(a)}^x g(t) \, dt$$

which is continuous at x , so G is differentiable and $G'(x) = g(x)$ by Theorem 1.3.2. Chain rule gives

$$\frac{d}{dx} G(f(x)) = g(f(x)) \cdot f'(x)$$

hence

$$\begin{aligned}\int_a^b g(f(x)) \cdot f'(x) \, dx &= \int_a^b G'(f(x)) \, dx = G(f(b)) - G(f(a)) \\ &= \int_{f(a)}^{f(b)} g(t) \, dt - \int_{f(a)}^{f(a)} g(t) \, dt \\ &= \int_{f(a)}^{f(b)} g(t) \, dt.\end{aligned}$$

□

Example 1.4.4.

$$\int_0^a e^{-\frac{x^2}{2}} x \, dx = \int_0^a e^{-\frac{x^2}{2}} \left(\frac{x^2}{2} \right)' \, dx.$$

Let $g(t) = e^{-t}$, $f(x) = \frac{x^2}{2}$. By theorem above the integral equals

$$\int_0^{\frac{a^2}{2}} e^{-t} \, dt = -e^{-t} \Big|_0^{\frac{a^2}{2}} = 1 - e^{-\frac{a^2}{2}}.$$

Remark (Consider integrals as functions of limits of integration). In the proof of the theorem above we established that: if f, h differentiable and g continuous, we have

$$\frac{d}{dx} \int_a^{f(x)} g(t) \, dt = g(f(x)) \cdot f'(x)$$

by chain rule, and similarly

$$\frac{d}{dx} \int_{h(x)}^a g(t) \, dt = -\frac{d}{dx} \int_a^{h(x)} g(t) \, dt = -g(h(x)) \cdot h'(x).$$

Example 1.4.5 (Construct solutions to certain PDEs). Let $f : \mathbb{R} \rightarrow \mathbb{R}$ be continuous, $b : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}$ be differentiable,

$$u : \mathbb{R} \times \mathbb{R} \rightarrow \mathbb{R}, (x, t) \mapsto \int_0^{b(x,t)} f(s) \, ds$$

where f continuous and b differentiable. Now consider the partial derivative, we have

$$\frac{\partial u(x, t)}{\partial x} = f(b(x, t)) \cdot \frac{\partial b}{\partial x}(x, t)$$

and

$$\frac{\partial u(x, t)}{\partial t} = f(b(x, t)) \cdot \frac{\partial b}{\partial t}(x, t)$$

by chain rule. Take $b(x, t) = x - ct$ where $c \in \mathbb{R}$ is a parameter. Then

$$\frac{\partial u(x, t)}{\partial x} + \frac{1}{c} \frac{\partial u(x, t)}{\partial t} = f(b(x, t)) \cdot 1 + \frac{1}{c} f(b(x, t))(-c) = 0,$$

i.e. a solution is found to the first-order linear PDE

$$\frac{\partial u}{\partial x} + \frac{1}{c} \frac{\partial u}{\partial t} = 0$$

parameterised by $f \in \mathcal{C}(\mathbb{R})$.

Example 1.4.6 (Integrals can be used to define new functions). The error function:

$$\operatorname{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt, \quad x \in \mathbb{R}.$$

where the integral is not computable, but FTC can be used to prove that erf is continuous. Or we could define $\log(0, \infty) \rightarrow \mathbb{R}$ in the following way:

$$x \mapsto \log(x) = \int_1^x \frac{1}{t} dt$$

which has properties

- well defined $\forall x > 0$;

•

$$\frac{d}{dx} \log(x) = \frac{d}{dx} \int_1^x \frac{1}{t} dt = \frac{1}{x}.$$

•

$$\begin{aligned} \log x + \log y &= \int_1^x \frac{1}{t} dt + \int_1^y \frac{1}{t} dt \\ &= \int_1^x \frac{1}{t} dt + \int_1^y \frac{1}{tx} dt \\ &= \int_1^x \frac{1}{t} dt + \int_x^{xy} \frac{1}{s} ds \quad \text{change of variable: } s(t) = xt \\ &= \int_1^{xy} \frac{1}{t} dt \\ &= \log(xy), \end{aligned}$$

which, as we've seen, was difficult to prove using power series definition of \log .

2 Improper integrals

Definition 2.0.1. Let $f : (a, b] \rightarrow \mathbb{R}$ be such that f is Riemann integrable on $[c, b] \forall c \in (a, b]$. Then

$$\underbrace{\int_a^b f}_{\text{Improper}} := \lim_{\varepsilon \downarrow 0} \underbrace{\int_{a+\varepsilon}^b f}_{\text{Riemann}},$$

which is a serious generalisation: f can be unbounded. If the limit exists and is finite, we say $\int_a^b f$ converges. Otherwise $\int_a^b f$ diverges.

Similarly, if $f : [a, b) \rightarrow \mathbb{R}$ is such that f is Riemann integrable on $[a, c] \forall c \in [a, b)$, then

$$\int_a^b f := \lim_{\varepsilon \downarrow 0} \int_a^{b-\varepsilon} f.$$

Example 2.0.2. Let $p > -1$, then

$$\begin{aligned}\int_0^1 x^p \, dx &= \lim_{\varepsilon \downarrow 0} \int_\varepsilon^1 x^p \, dx = \lim_{\varepsilon \downarrow 0} \left. \frac{x^{p+1}}{p+1} \right|_\varepsilon^1 \\ &= \lim_{\varepsilon \downarrow 0} \left(\frac{1}{p+1} - \underbrace{\frac{\varepsilon^{p+1}}{p+1}}_{\rightarrow 0 \text{ since } p+1 > 0} \right) \\ &= \frac{1}{p+1}.\end{aligned}$$

So $\int_0^1 x^p \, dx < \infty$ for $p > -1$, i.e. it converges. If $p = 1$,

$$\int_0^1 \frac{1}{x} \, dx = \lim_{\varepsilon \downarrow 0} \log x \Big|_\varepsilon^1 = \lim_{\varepsilon \downarrow 0} (-\log(\varepsilon)) = +\infty,$$

so it diverges.

Remark. If $p \geq 0$ we get the same answer: if f is integrable on $[a, b]$, then

$$\underbrace{\int_a^b f}_{\text{improper}} = \underbrace{\int_a^b f}_{\text{Riemann}}$$

by continuity, i.e. the two definitions are consistent.

Definition 2.0.3. Let $c \in (a, b)$ and $f : [a, b] \setminus \{c\} \rightarrow \mathbb{R}$ be Riemann integrable on $[a, c - \delta]$ and $[c + \varepsilon, b]$ for all $\delta > 0, \varepsilon > 0$ small enough.

Then

$$\int_a^b f := \underbrace{\int_a^c f}_{\text{improper}} + \underbrace{\int_c^b f}_{\text{improper}} = \lim_{\delta \downarrow 0} \int_a^{c-\delta} f + \lim_{\varepsilon \downarrow 0} \int_{c+\varepsilon}^b f$$

NB δ, ε are taken to 0 independently.

2.1 Unbounded intervals

Definition 2.1.1. $f : [a, \infty) \rightarrow \mathbb{R}$ such that f is integrable on $[a, b] \forall b \geq a$. Then

$$\int_a^\infty f := \lim_{b \uparrow \infty} \int_a^b f$$

and similarly if f is integrable on $[b, a] \forall b \leq a$

$$\int_{-\infty}^a f := \lim_{b \downarrow -\infty} \int_b^a f$$

and

$$\int_{-\infty}^\infty f := \underbrace{\int_{-\infty}^c f + \int_c^\infty f}_{\text{improper integrals defined above}} = \lim_{R_1 \rightarrow -\infty} \int_{R_1}^c f + \lim_{R_2 \rightarrow +\infty} \int_c^{R_2} f.$$

where $c \in \mathbb{R}$ any fixed constant.

NB $R_1 \rightarrow -\infty, R_2 \rightarrow +\infty$ independently.

Example 2.1.2.

$$\int_{-\infty}^\infty x^3 dx$$

doesn't exist. But

$$\lim_{R \rightarrow \infty} \int_{-R}^R x^3 dx = 0$$

and moreover, we can let R_2 be some function R_1 and right hand side can be whichever real number we want.

Exercise: check the RHS of the last definition does not depend on c .

Remark (Warnings). • The space of improperly integrable functions is a linear space, but not an algebra (in the sense that f, g improperly integrable $\nRightarrow f \cdot g$ is integrable). e.g.

$$f(x) = g(x) = \frac{1}{\sqrt{x}}, \quad x \in (0, 1]$$

are properly integrable since $p = \frac{1}{2} < 1$, but $x \mapsto \frac{1}{x}$ is not.

- Similarly, φ is continuous and f is improperly integrable $\nRightarrow \varphi \circ f$ is improperly integrable. e.g.

$$\varphi : y \mapsto y^2, \quad f : x \mapsto \frac{1}{\sqrt{x}}, \quad x \in (0, 1].$$

Then $\varphi(f(x)) = \frac{1}{x}$ which is again not integrable.

- f is improperly integrable $\nRightarrow |f|$ is improperly integrable. See notes and assignments.

Theorem 2.1.3 (Absolute comparison test). Let $f : [a, \infty) \rightarrow \mathbb{R}$ be Riemann integrable on $[a, b] \forall b \geq a$. Suppose

$$\int_a^\infty |f| < \infty.$$

Then

$$\int_a^\infty f < \infty.$$

In this case we say $\int_a^\infty f$ is absolutely convergent.

More generally, if there's a function $g : [a, \infty) \rightarrow [0, \infty)$ such that $|f| \leq g$, then

$$\int_0^\infty g < \infty \Rightarrow \int_a^\infty f < \infty.$$

Remark. 1. Compare this with the M -test for infinite series

2. Similar statements apply to improper integral of $f : [a, b] \setminus \{c\} \rightarrow \mathbb{R}$ where $c \in [a, b]$ which is not necessarily bounded

Proof. By Cauchy criterion, convergence of integral of $|f|$ implies that

$$\forall \varepsilon > 0, \exists L_\varepsilon : L_2 > L_1 > L_\varepsilon \Rightarrow \left| \int_a^{L_2} |f| - \int_a^{L_1} |f| \right| < \varepsilon.$$

But by additivity

$$\left| \int_a^{L_2} |f| - \int_a^{L_1} |f| \right| = \left| \int_{L_1}^{L_2} |f| \right| = \int_{L_1}^{L_2} |f|.$$

So

$$\left| \int_{L_1}^{L_2} f \right| \leq \int_{L_1}^{L_2} |f| < \varepsilon.$$

Therefore

$$\int_a^\infty f < \infty$$

by the reverse Cauchy criterion.

For the second part, repeat the above steps, simply replacing f with $|f|$ and $|f|$ with g . \square

Example 2.1.4. Does

$$\int_0^\infty \frac{\cos x^2}{1 + x^{1+\varepsilon}} dx$$

converge $\forall \varepsilon > 0$? We can't get rid of the $1 +$ in denominator since that would give a divergence, therefore we break it into two parts using additivity:

$$\underbrace{\int_0^1 \frac{\cos x^2}{1 + x^{\varepsilon+1}} dx}_{\text{Riemann integrable, so no need to worry}} + \int_1^\infty \frac{\cos x^2}{1 + x^{\varepsilon+1}} dx$$

and for the second part we have

$$\begin{aligned} \left| \int_1^\infty \frac{\cos x^2}{1 + x^{\varepsilon+1}} dx \right| &\leq \int_1^\infty \left| \frac{\cos x^2}{1 + x^{1+\varepsilon}} \right| dx = \int_1^\infty \overbrace{\frac{|\cos x^2|}{1 + x^{1+\varepsilon}}}^{\text{the } |f| \text{ in the theorem}} dx \\ &\leq \int_1^\infty \frac{1}{1 + x^{1+\varepsilon}} dx \leq \int_1^\infty \frac{1}{x^{1+\varepsilon}} dx \end{aligned}$$

and the last integral can be computed analytically:

$$-\frac{1}{\varepsilon}x^{-\varepsilon}\Big|_1^{\infty} = \frac{1}{\varepsilon} < \infty.$$

We conclude the desired result.

3 Sequences and series of functions

Main task: justify the interchange of maths operations.

Example 3.0.1.

$$\begin{aligned} \lim_{x \rightarrow c} \lim_{n \rightarrow \infty} f_n(x) &\stackrel{?}{=} \lim_{n \rightarrow \infty} \lim_{x \rightarrow c} f_n(x) \\ \lim_{n \rightarrow \infty} \int_a^b f_n(x) \, dx &\stackrel{?}{=} \int_a^b \lim_{n \rightarrow \infty} f_n(x) \, dx \\ \left(\sum_{n=1}^{\infty} f_n(x) \right)' &\stackrel{?}{=} \sum_{n=1}^{\infty} f_n'(x) \end{aligned}$$

3.1 Pointwise and uniform convergence

Let $f_n : \Omega \rightarrow \mathbb{R}, n \geq 1$ be a sequence of functions on $\Omega \subset \mathbb{R}$ (not necessarily closed bounded).

Definition 3.1.1 (Pointwise convergence). $(f_n)_{n \geq 1}$ on Ω converges to $f : \Omega \rightarrow \mathbb{R}$ *pointwise* if

$$\forall x \in \Omega, \lim_{n \rightarrow \infty} f_n(x) = f(x).$$

Notation. $f_n \rightarrow f$.

Remark. Pointwise convergence is often not enough to justify various interchanges. [If all you know is pointwise convergence, you do not know much.]

So sit tight for incoming examples of bad news!

Example 3.1.2. $f_n : [0, 1] \rightarrow \mathbb{R}, x \mapsto x^{\frac{1}{n}}$.

We know $f_n(0) = 0 \forall n$, and for $x \in (0, 1]$, $x^{1/n} = e^{\log x^{1/n}} = e^{\frac{1}{n} \log x} \rightarrow e^0 = 1$. So $f_n \rightarrow f =$
 $\begin{cases} 0 & x = 0 \\ 1 & \text{otherwise} \end{cases}$ which is not continuous. [Pointwise convergence doesn't preserve continuity!]
 So

$$\lim_{x \rightarrow 0+} \lim_{n \rightarrow \infty} f_n(x) = \lim_{x \rightarrow 0+} 1 = 1$$

but

$$\lim_{n \rightarrow \infty} \lim_{x \rightarrow 0+} f_n(x) = \lim_{n \rightarrow \infty} 0 = 0.$$

Example 3.1.3. Pointwise can be very non-uniform. Let

$$f_n(x) = \begin{cases} 2nx & 0 \leq x \leq \frac{1}{2n} \\ -2n \left(x - \frac{1}{n} \right) & \frac{1}{2n} < x \leq \frac{1}{n} \\ 0 & x > \frac{1}{n} \end{cases}$$

We claim that $f_n \rightarrow 0$. We know $f_n(0) = 0 \forall n \Rightarrow f(0) = 0$, but also

$$\forall x > 0, f_n(x) = 0 \forall n : \frac{1}{n} < x.$$

However

$$\sup_{x \in [0,1]} |f_n(x) - 0| = 1 \quad \forall n \in \mathbb{N}$$

which is constant and doesn't even depend on x ! Even worse, define

$$w_n = n f_n \quad (\text{Witch's hat})$$

Then $w_n \rightarrow 0$ still but

$$\sup_{x \in [0,1]} |w_n(x) - 0| = n$$

which goes to ∞ ! Pointwise convergence loses all its significance here.

Example 3.1.4. Let

$$f_n : \mathbb{R} \rightarrow \mathbb{R}, x \mapsto \underbrace{\mathcal{X}_{[n,n+1]}(x)}_{\text{Indicator function}}.$$

Then

$$\lim_{n \rightarrow \infty} \mathcal{X}_{[n,n+1]}(x) = 0 \quad \forall x \in \mathbb{R},$$

i.e. $\mathcal{X}_{[n,n+1]} \rightarrow 0$. What happens to the improper integral?

$$\lim_{n \rightarrow \infty} \int_{-\infty}^{\infty} \mathcal{X}_{[n,n+1]} = \lim_{n \rightarrow \infty} 1 \times 1 = 1$$

but

$$\int_{-\infty}^{\infty} \lim_{n \rightarrow \infty} \mathcal{X}_{[n,n+1]} = \int_{-\infty}^{\infty} 0 = 0.$$

Example 3.1.5. $f_n : x \mapsto \sin(nx)$ on \mathbb{R} , $n \in \mathbb{N}$. Take $x = \frac{p}{q}\pi$, $0 < p < q$, i.e. rational multiple of π . Then $\sin((kq)x) = \sin(pk\pi) = 0$ and $\sin((2kq+1)x) = \sin x > 0$ which converge to different limits. So we claim $(f_n) \not\rightarrow$. (Doesn't converge pointwise)

However for any $f \in [a, b]$ -Riemann integrable,

$$\lim_{n \rightarrow \infty} \int_a^b f(x) \sin(nx) \, dx = 0$$

(Riemann-Lebesgue Lemma).

Example 3.1.6. Let $g_n(x) := \frac{\sin nx}{n}$, $x \in \mathbb{R}$. Then $|g_n(x)| \leq \frac{1}{n} \rightarrow 0$. So $g_n \rightarrow 0$. Unlike the Witch's hat, even $\sup_{\mathbb{R}} |g_n| \rightarrow 0$. But

$$\left(\lim_{n \rightarrow \infty} g_n \right)' \neq \lim_{n \rightarrow \infty} g'_n = \lim_{n \rightarrow \infty} \cos nx$$

which doesn't exist.

Example 3.1.7. $(f_n) : [0, 1] \rightarrow \mathbb{R}$ defined in following way:

$$\begin{aligned} f_0 &= \mathcal{X}_{[0,1]}, \\ f_1 &= \mathcal{X}_{[0, \frac{1}{2}]}, f_2 = \mathcal{X}_{[\frac{1}{2}, 1]}, \\ f_3 &= \mathcal{X}_{[0, \frac{1}{4}]}, f_4 = \mathcal{X}_{[\frac{1}{4}, \frac{1}{2}]}, f_5 = \mathcal{X}_{[\frac{1}{2}, \frac{3}{4}]}, f_6 = \mathcal{X}_{[\frac{3}{4}, 1]}, \\ &\dots \end{aligned}$$

Note that $f_n \not\rightarrow$ as $\forall x \in [0, 1]$, $f_n(x)$ contains infinitely many 0's and 1's. However $\int_0^1 f_n \rightarrow 0$ since $\sup f = 1$ constantly but the size of subintervals goes to 0.

Definition 3.1.8 (Uniform convergence). A sequence $f_n : \Omega \rightarrow \mathbb{R}$, $n \geq 1$ *uniformly converges* to $f : \Omega \rightarrow \mathbb{R}$ if

$$\forall \varepsilon > 0, \exists \delta N_\varepsilon : n > N_\varepsilon \Rightarrow |f_n(x) - f(x)| < \varepsilon \quad \forall x \in \Omega.$$

Notation. • $f_n \Rightarrow f$.

- $f_n \not\Rightarrow$ means f_n does not converge uniformly.

- $\|f_n\|_\infty = \sup_\Omega |f_n|$. Left-hand side is called sup norm of f_n .

So $f_n \rightrightarrows f$ means that $\forall \varepsilon > 0, \exists N_\varepsilon : n > N_\varepsilon \Rightarrow \|f - f_n\|_\infty < \varepsilon$ or even simpler

$$\lim_{n \rightarrow \infty} \|f - f_n\|_\infty = 0.$$

Note that in this language, pointwise convergence can be written as

$$\lim_{n \rightarrow \infty} |f_n(x) - f(x)| = 0 \quad \forall x \in \Omega.$$

Proposition 3.1.9. $(f_n \rightrightarrows f) \not\Rightarrow (f_n \rightarrow f)$

This is trivial.

Definition 3.1.10. A sequence (f_n) on $\Omega \subset \mathbb{R}$ is *uniformly Cauchy* if

$$\forall \varepsilon > 0, \exists N_\varepsilon : n, m > N_\varepsilon \Rightarrow \|f_n - f_m\|_\infty < \varepsilon.$$

Theorem 3.1.11. $f_n \rightrightarrows$ on $\Omega \Leftrightarrow (f_n)$ is uniformly Cauchy.

Proof. \Rightarrow : Let $f : \Omega \rightarrow \mathbb{R}$ be the limit, i.e.

$$\forall \varepsilon, \exists N_\varepsilon : n > N_\varepsilon \Rightarrow \|f_n - f\|_\infty < \frac{\varepsilon}{2}.$$

Take any $n, m > N_\varepsilon$,

$$\begin{aligned} \|f_n - f_m\|_\infty &= \sup_\Omega |f_n - f_m| = \sup_\Omega |f_n - f + f - f_m| \\ &\leq \sup_\Omega (|f_n - f| + |f_m - f|) \quad \text{triangle inequality} \\ &\leq \sup_\Omega |f_n - f| + \sup_\Omega |f_m - f| = \|f_n - f\|_\infty + \|f_m - f\|_\infty \\ &< \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon. \end{aligned}$$

[We also proved triangle inequality for $\|\cdot\|_\infty$. Justified terminology!]

\Leftarrow : We have $\forall \varepsilon, \exists N_\varepsilon : n, m > N_\varepsilon \Rightarrow \sup_\Omega |f_n - f_m| < \varepsilon$. But $|f_n - f_m| \leq \sup_\Omega |f_n - f_m| \quad \forall x \in \Omega$ by definition, so $(f_m(x))$ is Cauchy, so it converges to $f(x)$ for some $f : \Omega \rightarrow \mathbb{R}$, i.e. $f_m \rightarrow f$ pointwise. We then write $\forall n, m > N_\varepsilon$,

$$f_m - \varepsilon \leq f_n \leq f_m + \varepsilon \text{ on } \Omega$$

(this is just rewriting the hypothesis of being Cauchy), then take $\lim_{m \rightarrow \infty}$ we have

$$f - \varepsilon \leq f_n \leq f + \varepsilon$$

so $|f_n - f| < \varepsilon \quad \forall x \in \Omega$ i.e. $f_n \rightrightarrows f$.

□

Remark. $\|\cdot\|_\infty$ is a norm on the space of bounded functions on Ω , denoted $\mathcal{B}(\Omega)$. Notion of a norm means that $\|\cdot\| : \mathcal{B}(\Omega) \rightarrow \mathbb{R}$ has following properties:

1. $\|f\|_\infty \geq 0 \ \forall f \in B(\Omega)$
2. $\|\lambda f\|_\infty = |\lambda| \|f\|_\infty \ \forall \lambda \in \mathbb{R}$
3. $\forall f, g \in B(\Omega), \|f + g\|_\infty \leq \|f\|_\infty + \|g\|_\infty$

Theorem 3.1.12 (Uniform continuity preserves continuity). A sequence of continuous functions $(f_n) : \Omega \rightarrow \mathbb{R}, n \geq 1$ converges uniformly to $f : \Omega \rightarrow \mathbb{R}$. Then f is continuous on Ω .

Proof. $f_n \rightrightarrows f$ means

$$\forall \varepsilon > 0, \exists N_\varepsilon : n > N_\varepsilon \Rightarrow \|f_n - f\|_\infty < \frac{\varepsilon}{3}. \quad (1)$$

Also f_n is continuous at $x_0 \in \Omega$, meaning

$$\forall \varepsilon > 0, \exists \delta_\varepsilon > 0 : |x - x_0| < \delta_\varepsilon^{(n)} \Rightarrow |f_n(x) - f_n(x_0)| < \frac{\varepsilon}{3}. \quad (2)$$

Fix any $n > N_\varepsilon$ and $\delta_\varepsilon^{(n)} > 0$. Then

$$\begin{aligned} |f(x) - f(x_0)| &= |f(x) - f_n(x) + f_n(x) - f_n(x_0) + f_n(x_0) - f(x_0)| \\ &\leq \underbrace{|f(x) - f_n(x)|}_{< \frac{\varepsilon}{3} \text{ by (1)}} + \underbrace{|f_n(x) - f_n(x_0)|}_{< \frac{\varepsilon}{3} \text{ by (2)}} + \underbrace{|f_n(x_0) - f(x_0)|}_{< \frac{\varepsilon}{3} \text{ by (1)}} \\ &< 3 \cdot \frac{\varepsilon}{3} = \varepsilon \end{aligned}$$

□

Notation. $\mathcal{C}_b(\Omega, \|\cdot\|_\infty)$ is a linear space of continuous, bounded functions on Ω , equipped with $\|\cdot\|_\infty$ norm. (∞ -dim normed space)

Theorem 3.1.13 (Completeness). $\mathcal{C}_b(\Omega, \|\cdot\|_\infty)$ is a complete normed space, i.e. any Cauchy sequence $(f_n) \subset \mathcal{C}_b(\Omega)$ converges to some $f \in \mathcal{C}_b(\Omega)$.

Without using all the jargon: a uniformly Cauchy sequence of continuous bounded functions converges to a continuous and bounded function.

Remark. A Cauchy sequence $(a_n) \subset \underbrace{(V, \|\cdot\|)}_{\text{normed space}}$ is such that

$$\forall \varepsilon > 0, \exists N_\varepsilon : n, m > N_\varepsilon \Rightarrow \|a_n - a_m\| < \varepsilon.$$

This definition ensures that the two formulated versions of Theorem 3.1.13 are equivalent.

Proof. $f_n \rightrightarrows f$ and f_n is continuous $\forall n$, so by Theorem 3.1.12 f is continuous.

We can pick $n : \|f - f_n\|_\infty \leq 1$. Then

$$\|f\|_\infty \|f_n + f - f_n\|_\infty \leq \|f_n\|_\infty + \|f - f_n\|_\infty < \infty + 1 = \infty.$$

Therefore f is also bounded. □

Example 3.1.14. $f_n = \frac{1}{2n} \mathcal{X}_{[-n, n]}$ on \mathbb{R} . Then $\|f_n\|_\infty = \frac{1}{2n} \rightarrow 0$. So $f_n \rightrightarrows 0$. And $\int_{-\infty}^{\infty} f_n = 1 \neq \int_{-\infty}^{\infty} \lim_{n \rightarrow \infty} f_n$. But good news is on bounded interval this inequality does not occur.

Theorem 3.1.15. $f_n : [a, b] \rightarrow \mathbb{R}$ is integrable $\forall n$ and $f_n \rightrightarrows f : [a, b] \rightarrow \mathbb{R}$. Then f is integrable and $\int_a^b f_n \rightarrow \int_a^b f$. (i.e.

$$\lim_{n \rightarrow \infty} \int_a^b f_n = \int_a^b \lim_{n \rightarrow \infty} f_n,$$

limit and integral is interchangeable in this case.)

Proof. Uniform convergence means

$$\forall \varepsilon > 0, \exists N_\varepsilon : n > N_\varepsilon \Rightarrow \|f - f_n\|_\infty < \frac{\varepsilon}{4(b-a)}.$$

Integrability $\forall n$ means

$$\forall \varepsilon > 0, \exists P_n \in \mathcal{P} : U(f_n, P_n) - L(f_n, P_n) < \frac{\varepsilon}{2},$$

where we let $P_n = \{I_1, \dots, I_m\}$. Fix $n > N_\varepsilon$. Then

$$U(f_n, P_n) - L(f_n, P_n) = \sum_{k=1}^m \left(\sup_{I_k} f - \inf_{I_k} f \right) |I_k|.$$

Side computation:

$$\begin{aligned} \sup_{I_k} f &= \sup_{I_k} (f_n + f - f_n) \\ &\leq \sup_{I_k} f_n + \sup_{I_k} (f - f_n) \\ &\leq \sup_{I_k} f_n + \sup_{I_k} |f - f_n| \\ &\leq \sup_{I_k} f_n + \|f - f_n\|_\infty. \end{aligned}$$

Similarly we can get a lower bound for $\inf_{I_k} f$, namely $\inf_{I_k} f_n - \|f - f_n\|_\infty$. So

$$\begin{aligned} \sum_{k=1}^m \left(\sup_{I_k} f - \inf_{I_k} f \right) |I_k| &\leq \underbrace{\sum_{k=1}^m \left(\sup_{I_k} f_n - \inf_{I_k} f_n \right) |I_k|}_{< \frac{\varepsilon}{2} \text{ by integrability}} + 2 \sum_{i=1}^m \underbrace{\|f - f_n\|_\infty}_{< \frac{\varepsilon}{4(b-a)} \text{ by uniform convergence}} |I_k| \\ &< \frac{\varepsilon}{2} + 2 \frac{\varepsilon}{4(b-a)} (b-a) = \varepsilon, \end{aligned}$$

which implies integrability of f .

Now

$$\begin{aligned} \left| \int_a^b f_n - \int_a^b f \right| &\leq \int_a^b |f_n - f| \\ &\leq \int_a^b \|f_n - f\|_\infty \quad \text{this is why we need bounded} \\ &= \underbrace{\|f_n - f\|_\infty}_{\rightarrow 0} (b-a). \end{aligned}$$

So $\int_a^b f_n \rightarrow \int_a^b f$. □

3.2 Functions of 2 variables

Definition 3.2.1. $f : \Omega \subset \mathbb{R}^2 \rightarrow \mathbb{R}$ is *continuous* at $x \in \Omega$ if

$$\forall \varepsilon > 0, \exists \delta(\varepsilon, x) > 0 : (y \in \Omega, \underbrace{|x - y|}_{\text{Euclidean distance}} < \delta) \Rightarrow \underbrace{|f(x) - f(y)|}_{\text{absolute value}} < \varepsilon.$$

This is the same with previous definition of continuity, only 2-variable.

Definition 3.2.2. $f : \Omega \subset \mathbb{R}^2 \rightarrow \mathbb{R}$ is *uniformly continuous* on Ω if

$$\forall \varepsilon > 0, \exists \delta_\varepsilon : (x, y \in \Omega : |x - y| < \delta_\varepsilon) \Rightarrow |f(x) - f(y)| < \varepsilon.$$

This is the same with Definition 1.1.13.

Theorem 3.2.3. $\Omega \subset \mathbb{R}^2$ closed and bounded. If $f : \Omega \rightarrow \mathbb{R}$ is continuous then it's uniformly continuous.

Hint for proof. Use Bolzano-Weierstrass theorem for bounded sequences in \mathbb{R}^2 . (Similar to proof of Theorem 1.1.14.) \square

Theorem 3.2.4. Let $f : [a, b] \times [c, d] \rightarrow \mathbb{R}$ be continuous. Define $I : [c, d] \rightarrow \mathbb{R}, t \mapsto \int_a^b f(x, t) \, dx$. Then I is continuous on $[c, d]$.

Proof. We know $[a, b] \times [c, d]$ is closed and bounded. Then f is uniformly continuous. Fix any $t_0 \in [c, d]$. Then

$$|I(t) - I(t_0)| \leq \int_a^b |f(x, t) - f(x, t_0)| \, dx.$$

Uniform continuity means $\forall \varepsilon > 0, \exists \delta_\varepsilon > 0 :$

$$(|(x, t) - (x_0, t_0)| < \delta_\varepsilon, (x, t), (x_0, t_0) \in [a, b] \times [c, d]) \Rightarrow |f(x, t) - f(x_0, t_0)| < \frac{\varepsilon}{b - a}.$$

Now pick any $t : |t - t_0| < \delta_\varepsilon$. Then $|(x, t_0) - (x, t)| < \delta_\varepsilon$. So

$$|I(t) - I(t_0)| < \int_a^b \frac{\varepsilon}{b - a} = \varepsilon,$$

i.e. I is continuous at t_0 by definition. \square

Theorem 3.2.5. $f, \frac{\partial f}{\partial t} : [a, b] \times [c, d] \rightarrow \mathbb{R}$ are continuous. Then $t \mapsto \int_a^b f(x, t) \, dx$ is differentiable on $[c, d]$ and

$$\frac{\partial}{\partial t} \int_a^b f(x, t) \, dx = \int_a^b \frac{\partial}{\partial t} f(x, t) \, dx.$$

Proof. Define

$$F(t) := \int_a^b f(x, t) \, dx$$

and

$$G(t) := \int_a^b \frac{\partial f}{\partial t}(x) \, dx.$$

We would like to show that F is differentiable on (c, d) and $F' = G$.

We write

$$\left| \frac{F(t+h) - F(t)}{h} - G(t) \right| dx = \left| \int_a^b \frac{f(x, t+h) - f(x, t)}{h} - G(t) \right| dx$$

and since $f(x, \cdot)$ is continuous and differentiable on $[c, d]$, we can apply MVT and the above is

$$\left| \int_a^b \frac{\partial f}{\partial t}(x, \tau) - \frac{\partial f}{\partial t}(x, t) \right| dx$$

for some $\tau \in [t, t+h]$. But $\frac{\partial f}{\partial t}$ is continuous on closed bounded interval $[a, b] \times [c, d]$, so we have uniform continuity. Therefore $\forall \varepsilon > 0, \exists \delta_\varepsilon$:

$$|\tau - t| < \delta_\varepsilon \Rightarrow \left| \frac{\partial f}{\partial t}(x, \tau) - \frac{\partial f}{\partial t}(x, t) \right| < \frac{\varepsilon}{b-a}.$$

So pick $|h| < \delta_\varepsilon$, we have

$$\left| \frac{F(t+h) - F(t)}{h} - G(t) \right| dx < \int_a^b \frac{\varepsilon}{b-a} dx = \varepsilon.$$

Take $\limsup_{h \rightarrow 0}$ and $\liminf_{h \rightarrow 0}$ of $\frac{F(t+h) - F(t)}{h}$. They are equal to each other since ε is arbitrary. So

$$\lim_{h \rightarrow 0} \frac{F(t+h) - F(t)}{h} = G(t).$$

□

Theorem 3.2.6 (Fubini). Let $f : [a, b] \times [c, d] \rightarrow \mathbb{R}$ be continuous. Then

$$\int_a^b \left(\int_c^d f(x, y) dy \right) dx = \int_c^d \left(\int_a^b f(x, y) dx \right) dy.$$

Example 3.2.7 (Why is this useful?). Consider $F : [0, \infty) \times \mathbb{R} \rightarrow \mathbb{R}$ continuous. Fix any $n \in \mathbb{N}$, $c \in \mathbb{R}_+$. Then $(x, y) \mapsto x^{2n+1}F(x^2, y)$ is continuous. We want to calculate

$$\int_{-c}^c \left(\int_a^b x^{2n+1}F(x^2, y) dy \right) dx.$$

But x^{2n+1} is odd, so is $x^{2n+1}F$, so $\int_{-c}^c x^{2n+1}F(x^2, y) dx$ is zero. Using Fubini we reverse the order and answer is immediately 0.

Proof. Define

$$x \mapsto \int_c^d f(x, y) dy$$

and

$$y \mapsto \int_a^b f(x, y) dx.$$

They are continuous and therefore integrable by Theorem 3.2.4. So both sides of the theorem are well-defined.

Let

$$F(t) := \int_a^t \left(\int_c^d f(x, y) \, dy \right) dx - \int_c^d \left(\int_a^t f(x, y) \, dx \right) dy,$$

where $t \in [a, b]$. We would like to show that $F(b) = 0$.

What do we know?

1. $F(a) = 0$ by conventional generalisation of FTC
2. $F \in \mathcal{C}[a, b]$, since both terms are continuous, first by FTC, second: $(t, y) \mapsto \int_a^t f(x, y) \, dx$ is continuous as a function of 2 variables: since f is continuous therefore uniformly continuous, in particular f is bounded, i.e. $\exists M > 0 : |f| \leq M$. We write

$$\begin{aligned} \left| \int_a^t f(x, y) \, dx - \int_a^{t_0} f(x, y_0) \, dx \right| &= \left| \int_a^t (f(x, y) - f(x, y_0)) \, dx - \int_t^{t_0} f(x, y_0) \, dx \right| \\ &\leq \int_a^t |f(x, y) - f(x, y_0)| \, dx + \left| \int_t^{t_0} f(x, y_0) \, dx \right| \\ &\leq \underbrace{\int_a^t |f(x, y) - f(x, y_0)| \, dx}_{\text{estimate it with uniform continuity of } f} + M \underbrace{|t - t_0|}_{\rightarrow 0}. \end{aligned}$$

So by Theorem 3.2.4 second term is continuous.

3. By FTC derivative of $t \mapsto \int_a^t \left(\int_c^d f(x, y) \, dy \right) dx$ is $\int_c^d f(t, y) \, dy$, and by Theorem 3.2.5 derivative of $t \mapsto \int_c^d \left(\int_a^t f(x, y) \, dx \right) dy$ is equal to

$$\int_c^d \left(\frac{\partial}{\partial t} \int_a^t f(x, y) \, dx \right) dy = \int_c^d f(t, y) \, dy.$$

$$\text{So } F'(t) = \int_c^d f(t, y) \, dy - \int_c^d f(t, y) \, dy = 0.$$

Therefore by MVT $F(b) = 0$. □

Example 3.2.8 (Without some assumptions about $(x, y) \mapsto f(x, y)$ Fubini fails). Let

$$I := \int_0^1 \left(\int_0^1 \frac{x^2 - y^2}{(x^2 + y^2)^2} \, dy \right) dx$$

where the 2-variable function is not continuous no matter how you assign the values when $x = y = 0$. So consider f defined on $(0, 1] \times (0, 1]$ and treat the integrals as improper integrals. Doing it in the defined order we have

$$\int_0^1 \left(\frac{y}{x^2 + y^2} \Big|_{y=0}^{y=1} \right) dx = \int_0^1 \frac{1}{1 + x^2} \, dx = \frac{\pi}{4},$$

(do a change of variable: let $x(t) = \tan^{-1}(t)$ to get the result), but reversing it we have, by symmetry, $-\frac{\pi}{4}$.

Notation. C^n means set of continuous functions that are n time differentiable with its n -th derivative continuous.

Example 3.2.9 (Motivation for next theorem). We already know $f_n \rightrightarrows f$ doesn't imply that f is differentiable. Moreover, take

$$f_n(x) = \left(x^2 + \frac{1}{n}\right)^{\frac{1}{2}} \in C^\infty(\mathbb{R}),$$

then $f_n \rightrightarrows |x|$ since we can bound $x^2 + \frac{1}{n}$ by $\left(|x| + \frac{1}{\sqrt{n}}\right)^2$ and we have

$$f_n(x) - |x| \leq |x| + \frac{1}{\sqrt{n}} - |x| = \frac{1}{\sqrt{n}} \rightarrow 0 \quad \forall x \in \mathbb{R}.$$

But $|x|$ is not differentiable at 0.

Theorem 3.2.10. $(f_n) \subset C^1[a, b]$. Suppose $f_n \rightarrow f : [a, b] \rightarrow \mathbb{R}$ and $f'_n \rightrightarrows g : [a, b] \rightarrow \mathbb{R}$. Then $f \in C^1[a, b]$ and $f' = g$.

In other words,

$$\left(\lim_{n \rightarrow \infty} f_n\right)' = \lim_{n \rightarrow \infty} f'_n.$$

Proof. We have $(f'_n) \subset C[a, b]$. Since g is the uniform limit, $g \in C[a, b]$ is integrable. We write

$$\int_a^x g = \int_a^x \lim_{n \rightarrow \infty} f'_n \quad \underbrace{=}_{\text{Theorem 3.1.15}} \lim_{n \rightarrow \infty} \int_a^x f'_n \quad \underbrace{=}_{\text{FTC}} \lim_{n \rightarrow \infty} (f_n(x) - f_n(a)) = f(x) - f(a),$$

i.e. $f(x) = f(a) + \int_a^x g$, so $f'(x) = g(x)$ by FTC. Since g is continuous, $f \in C^1[a, b]$. \square

3.3 Series of functions

Let (f_n) be a sequence of functions on Ω . Then a series of functions is also a function

$$x \mapsto \sum_{n=1}^{\infty} f_n(x), \quad x \in \Omega.$$

Definition 3.3.1. Let

$$S_n := \sum_{k=1}^n f_k : \Omega \rightarrow \mathbb{R}, \quad n \geq 1$$

be the sequence of partial sums. We say that $\sum_{k=1}^{\infty} f_k$ converges to $S : \Omega \rightarrow \mathbb{R}$ pointwise (uniformly) if $S_n \rightarrow (\Rightarrow) S$.

Theorem 3.3.2. Let (f_n) be a sequence of integrable functions on $[a, b]$ such that $\sum_{k=1}^{\infty} f_k$ converges uniformly. Then

$$\sum_{k=1}^{\infty} f_k : [a, b] \rightarrow \mathbb{R}$$

is integrable and

$$\int_a^b \sum_{k=1}^{\infty} f_k = \sum_{k=1}^{\infty} \int_a^b f_k.$$

i.e. series can be integrated term by term.

Proof. Consider

$$S_n := \sum_{k=1}^n f_k, \quad S := \sum_{k=1}^{\infty} f_k$$

and we know $S_n \Rightarrow S$. By linearity S_n is integrable. By Theorem 3.1.15, S is then integrable, and moreover

$$\int_a^b S = \lim_{n \rightarrow \infty} \int_a^b S_n.$$

So

$$\int_a^b \sum_{k=1}^{\infty} f_k = \lim_{n \rightarrow \infty} \int_a^b \sum_{k=1}^n f_k \underset{\text{linearity}}{=} \lim_{n \rightarrow \infty} \sum_{k=1}^n \int_a^b f_k = \sum_{k=1}^{\infty} \int_a^b f_k.$$

□

Example 3.3.3 (Do everything by hand). Let $\lambda > 0$ and define

$$S(x) := \sum_{k=1}^{\infty} e^{-\lambda k x}, \quad x \in [1, \infty).$$

What is $\int_1^{\infty} S$?

Notice that the series converges uniformly on $[1, \infty)$: let

$$S_n(x) := \sum_{k=1}^n e^{-\lambda k x},$$

then

$$|S_n(x) - S_m(x)| = \left| \sum_{k=m+1}^n e^{-\lambda k x} \right| \leq e^{-\lambda m} \left| \sum_{k=0}^{\infty} e^{-\lambda k \cdot 1} \right| \rightarrow 0$$

since it's geometric. So it's Cauchy therefore it's uniformly convergent. Therefore we can integrate it term by term:

$$\begin{aligned}\int_1^\infty S &= \int_1^\infty \sum_{k=1}^\infty e^{-\lambda k x} dx = \sum_{k=1}^\infty \int_1^\infty e^{-\lambda k x} dx \\ &= \sum_{k=1}^\infty \frac{1}{\lambda k} e^{-\lambda k} = \frac{1}{\lambda} \sum_{k=1}^\infty \frac{1}{k} (e^{-\lambda})^k \\ &= \frac{1}{\lambda} \log(1 - e^{-\lambda}).\end{aligned}$$

Checking that applying Theorem 3.3.2 here to improper integrals is legitimate is left as an exercise.

Remark. We can then integrate any function given by uniformly convergent Taylor or Fourier series and set the answer as an infinite sum.

Theorem 3.3.4. $(f_k) \subset C^1[a, b] : \sum_{k=1}^\infty f_k$ converges pointwise and $\sum_{k=1}^\infty f'_k$ converge uniformly.

Then

$$x \mapsto \sum_{k=1}^\infty f_k \in C^1[a, b]$$

and

$$\left(\sum_{k=1}^\infty f_k \right)' = \sum_{k=1}^\infty f'_k.$$

i.e. series can be differentiated term by term.

Proof. Let

$$S_n := \sum_{k=1}^n f_k, \quad S := \sum_{k=1}^\infty f_k$$

Given that $S_n \rightarrow S$, $S'_n \rightrightarrows g$, we have, by Theorem 3.2.10, $S \in C^1[a, b]$ and $S' = \lim_{n \rightarrow \infty} S'_n$.

We use the fact that $(f_n) \subset C^1[a, b] \Rightarrow S_n \in C^1[a, b]$ (algebra of differentiable functions).

Therefore

$$\left(\sum_{k=1}^n f_k \right)' = \lim_{n \rightarrow \infty} \sum_{k=1}^n f'_k = \sum_{k=1}^\infty f'_k.$$

□

Theorem 3.3.5 (Weierstrass M -test). Let (f_k) be a sequence of functions on $\Omega \subset \mathbb{R}$. Suppose $\forall k \in \mathbb{N}, \exists M_k \geq 0 : |f_k| \leq M_k$ where $\sum_{k=1}^\infty M_k < \infty$. Then $\sum_{k=1}^\infty f_k$ converges uniformly on Ω .

Proof.

$$\sum_{k=1}^\infty M_k < \infty$$

if and only if $\left(\sum_{k=1}^n M_k\right)$ is Cauchy if and only if

$$\forall \varepsilon > 0, \exists N_\varepsilon : n, m > N_\varepsilon \Rightarrow \left| \sum_{k=1}^n M_k - \sum_{k=1}^m M_k \right| < \varepsilon.$$

Then $\forall x \in \Omega$,

$$|S_n(x) - S_m(x)| = \left| \sum_{k=m+1}^n f_k(x) \right| \leq \sum_{k=m+1}^n |f_k(x)| \leq \sum_{k=m+1}^n M_k < \varepsilon.$$

Therefore (S_n) is Cauchy, therefore uniformly convergent. \square

3.4 3 non-examinable (but exciting!) topics

3.4.1 Continuous but nowhere differentiable functions

Natural example: trajectory of a Brownian particle (sample path of a stochastic process known as Brownian motion)

We will explain construction of the Weierstrass function (1872).

The starting point:

$$\phi : \mathbb{R} \rightarrow \mathbb{R}, \quad x \mapsto \text{dist}(x, \mathbb{Z})$$

Our function will be constructed as a limit of the series of piecewise linear functions built out of ϕ .

Remark. Lévy (1950) used this idea for his rigorous construction of Brownian motion.

It's sometimes called the Sawtooth function.

Obvious properties:

1. ϕ is continuous
2. ϕ is periodic, i.e. $\phi(x+1) = \phi(x) \forall x \in \mathbb{R}$

3. ϕ is piecewise linear
4. $\phi'(x) \in \{\pm 1\}$ at all x where ϕ' is defined

We can write a formula:

$$\phi(x) = \begin{cases} x - [x], & [x] \leq x[x] + \frac{1}{2} \\ [x] + 1 - x, & [x] + \frac{1}{2} < x < [x] + 1 \end{cases}$$

Now define Weierstrass function

$$f : \mathbb{R} \rightarrow \mathbb{R}, \quad x \mapsto \sum_{n=0}^{\infty} f_n(x), \quad n > 0$$

where $f_n(x) = \frac{1}{4^n} \phi(4^n x)$. So property 4 still holds, f_0 is just ϕ , and f_1 is drawn in the same plot above.

Claim. f is continuous on \mathbb{R} .

Proof. We know $\|\phi\|_{\infty} = \frac{1}{2}$ and

$$\|f_n\| = \left\| \frac{1}{4^n} \phi(4^n x) \right\|_{\infty} = \frac{1}{4^n} \sup_{\mathbb{R}} |\phi(4^n x)| = \frac{1}{4^n} \sup_{\mathbb{R}} |\phi| = \frac{1}{4^n} \cdot \frac{1}{2} < \frac{1}{4^n}.$$

Moreover,

$$\sum_{k=0}^{\infty} \frac{1}{4^k} < \infty \quad (\text{geometric}),$$

therefore $\sum_{k=0}^{\infty} f_k$ converges uniformly on \mathbb{R} by his own M -test. So

$$\sum_{k=0}^n f_k \Rightarrow \sum_{k=0}^{\infty} f_k = f$$

and f is continuous by continuity of f_k . □

Claim. f is nowhere differentiable.

Proof. We would like to show that for any $x_0 \in \mathbb{R}$,

$$\lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h}$$

doesn't exist. It suffices to show that we can find a sequence $(h_n)_{n \geq 0} \subset \mathbb{R}$ such that

1. $h_n \rightarrow 0$,
2. $\lim_{h_n \rightarrow 0} \frac{f(x+h_n) - f(x)}{h_n}$ doesn't exist.

Define $h_n = \pm \frac{1}{4^{n+1}}$ where the sign is chosen carefully in such a way that

$$4^n x_0, 4^n(x_0 + h_n) \in \left[k, k \pm \frac{1}{2} \right]$$

for some $k \in \mathbb{Z}$. (These points belong either to $[k - \frac{1}{2}, k]$ or $[k, k + \frac{1}{2}]$ for some integer k . The above is just shorthand notation. In particular, we are choosing the sign so that the two points are not separated by a point at which the function is not differentiable.)

Then clearly $\lim_{n \rightarrow \infty} h_n = 0$, and $f_n|_{[x_0, x_0 + h_n]}$ has a constant slope equal to ± 1 . We then write

$$\frac{f_n(x_0 + h_n) - f_n(x_0)}{h_n} = \frac{\phi(4^n x_0 + 4^n h_n) - \phi(4^n x_0)}{4^n h_n} \in \{\pm 1\}. \quad (3)$$

Now fix $m \geq n + 1$, and we have

$$\frac{f_m(x_0 + h_n) - f_m(x_0)}{h_n} = \frac{\phi(4^m x_0 + \overbrace{4^m h_n}^{\in \mathbb{Z}}) - \phi(4^m x_0)}{4^m h_n} = 0 \quad (4)$$

since ϕ is periodic with period 1. And for $m < n$, if f_m is not smooth at points x , i.e.

$$4^m x = \frac{k}{2} \quad \text{for } k \in \mathbb{Z},$$

then for the same x ,

$$4^n x = 4^{n-m}(4^m x) = 4^{n-m} \left(\frac{k}{2} \right) = \frac{k'}{2}$$

where $k' = 4^{n-m} \cdot k$, $n \geq m$. This means if m is not smooth then n is not either.

We conclude that the set of points at which f_m changes slope is a subset of points where f_n changes slope, $n \geq m$. Also, if $f_n|_{[x_0, x_0 + h_n]}$ has constant slope then so does $f_m|_{[x_0, x_0 + h_n]}$, $n \geq m$.

In plain English, the indifferentiable points of f_n are also indifferentiable points of f_{n+1} . Finally, we write

$$\begin{aligned}\frac{f(x+h_n) - f(x_n)}{h_n} &= \lim_{N \rightarrow \infty} \sum_{m=0}^N \frac{f_m(x_0+h_n) - f_m(x_0)}{h_n} \\ &= \sum_{m=0}^n \frac{f_m(x_0+h_n) - f_m(x_0)}{h_n} \quad \text{by (4)} \\ &= \sum_{m=0}^n \varepsilon_m \quad \text{by (3)}\end{aligned}$$

where $\varepsilon_m \in \{\pm 1\}$. Taking the limits to get to derivative, we have

$$\lim_{n \rightarrow \infty} \frac{f(x+h_n) - f(x_n)}{h_n} = \sum_{m=0}^{\infty} \varepsilon_m$$

which diverges! Hence desired result. \square

3.4.2 Space-filling curves

Aim: construct a surjective, continuous map from $[0, 1]$ to $[0, 1] \times [0, 1]$.

Surjective is not that hard: define $\gamma_0 : [0, 1] \rightarrow [0, 1]^2$ like this: write numbers in $[0, 1]$ as $0.a_1a_2a_3\dots$ where $a_i \in \{0, 1, \dots, 9\}$. Then take the two subsequences and form an ordered pair, an odd and an even: $(0.a_1a_3a_5\dots, 0.a_2a_4a_6\dots)$. It's in fact bijective.

But it's not continuous! So is it possible to reach the aim? The answer is of course positive.

We will review Hilbert's construction of the curve (1891), the very first example is due to Peano (1890), as a uniformly convergent sequence of piecewise linear curves.

Terminology:

- A *curve* in \mathbb{R}^2 is a continuous map $\beta : [0, 1] \rightarrow \mathbb{R}^2$, $t \mapsto \beta(t) = (\beta_1(t), \beta_2(t))$
- It's useful recalling that β is *continuous* at $t_0 \in [0, 1]$ if

$$\forall \varepsilon > 0, \exists \delta_\varepsilon > 0 : |t - t_0| < \delta_\varepsilon \Rightarrow |\beta(t) - \beta(t_0)| < \varepsilon,$$

and this if and only if $\beta_1, \beta_2 : \mathbb{R} \rightarrow \mathbb{R}$ are continuous

- The *image* of β , $\text{Im}(\beta) = \beta([0, 1]) \subset \mathbb{R}^2$
- A curve $\gamma : [0, 1] \rightarrow [0, 1]^2$ is called *space-filling* or SPC if $\text{Im}(\gamma) = [0, 1]^2$.

We now define the Hilbert curve

$$\gamma := \lim_{n \rightarrow \infty} \gamma_n$$

where $\gamma_n \Rightarrow \gamma$. And here's the construction. Denote unit square as S_0 .

1. Divide into four, connect centres of squares counterclockwise, and connect the two top centres with two vertices. Before parameterising γ_1 , we label the smaller squares as $S_{0,0}, S_{0,1}, S_{0,2}, S_{0,3}$ counterclockwise. Now notice $S_{0,n} \subset S_0$. We want our parametrisation

satisfies that $\gamma_1([0, \frac{1}{4}]) \subset S_{0,0}$, $\gamma_1([\frac{1}{4}, \frac{1}{2}]) \subset S_{0,1}$, $\gamma_1([\frac{1}{2}, \frac{3}{4}]) \subset S_{0,2}$, $\gamma_1([\frac{3}{4}, 1]) \subset S_{0,3}$. We can then write:

$$\gamma_1(t) = \begin{cases} (2t, 1 - 2t), & 0 \leq t < \frac{1}{8} \\ (\frac{1}{4}, 1 - 2t), & \frac{1}{8} \leq t < \frac{3}{8} \\ (2t - \frac{1}{2}, \frac{1}{4}), & \frac{3}{8} \leq t < \frac{5}{8} \\ (\frac{3}{4}, 2t - 1), & \frac{5}{8} \leq t < \frac{7}{8} \\ (2t - 1, 2t - 1), & \frac{7}{8} \leq t \leq 1 \end{cases}$$

γ_1

2. Now create 4 copies of $\text{Im}(\gamma_1)$ and connect them together in 4 divided squares to create γ_2 :

γ_2

The lower two are just translations, but we have to rotate for the upper two ($\frac{\pi}{2}$ counter-clockwise and clockwise respectively) to keep the curve starting from top left and end at top right. To make sure the direction of parameterisation makes sense, we also have to reflect horizontally. And finally we need to scale it down by a factor of 2 to make it a unit square.

We again, as before, enumerate the 4 squares of size $\frac{1}{2} \times \frac{1}{2}$ as $S_{0,m}$, $0 \leq m \leq 3$. We also have 16 squares of size $\frac{1}{4} \times \frac{1}{4}$, and we enumerate them as $S_{0,m_1 m_2}$, $0 \leq m_1, m_2 \leq 3$, where m_1 is the index of the $\frac{1}{2} \times \frac{1}{2}$ squares and m_2 is similar to m as in how we enumerate $S_{0,m}$'s. Note

$$S_{0,m_1,m_2} \subset S_{0,m_1} \quad \forall m_1, m_2.$$

For parametrisation of γ_2 , we notice

$$\gamma_2(t) = \begin{cases} A_0\gamma_1(4t), & 0 \leq t \leq \frac{1}{4} \\ A_1\gamma_1(4t-1), & \frac{1}{4} \leq t \leq \frac{1}{2} \\ A_2\gamma_1(4t-2), & \frac{1}{2} \leq t \leq \frac{3}{4} \\ A_3\gamma_1(4t-3), & \frac{3}{4} \leq t \leq 1 \end{cases},$$

(basically speed it up in the smaller squares and impose lags to make sure every part of it satisfy the original parametrisation with t ranging from 0 to 1). So we don't need to invent a new parametrisation. Notice γ_2 goes through all 16 squares and spend $\frac{1}{16}$ of the time in each of it. Let us treat $0.m_1m_2$ now as quaternary fractions:

$$0.m_1m_2 = m_1 \times 4^{-1} + m_2 \times 4^{-2} = \frac{m_1}{4} + \frac{m_2}{16},$$

since we keep dividing by 4, it's better to use base 4 than base 10. Notice by construction

$$\gamma_2 \left([m_1m_2, m_1m_2 + 1] \frac{1}{4^2} \right) \subset S_{0.m_1m_2}$$

where m_1m_2 , a quaternary number, is equal to $m_1 \times 4^1 + m_2 \times 4^0 = 4m_1 + m_2$.

- Now we can construct γ_{n+1} from γ_n generally, in a way exactly the same as how γ_2 is constructed from γ_1 : enumerate counterclockwise, translate, rotate, reflect and scale. And we have a new index for smallest squares, namely $S_{0.m_1m_2\dots m_n}$. Note $S_{0.m_1\dots m_n} \subset S_{0.m_1\dots m_k}$ for any $k \leq n$. Parametrisation of γ_{n+1} is again recursive like what we wrote for γ_2 .

Now we have $\gamma_n : [0, 1] \rightarrow [0, 1]^2$ such that

- it's piecewise linear, continuous, passing through centre of each 4^n squares of size $\frac{1}{2^n}$
- $\gamma_n \left([0.m_1\dots m_n, 0.m_1\dots m_n + \frac{1}{4^n}] \right) \subset S_{0.m_1\dots m_n}$.

We need to establish

- The limit $\lim_{n \rightarrow \infty} \gamma_n$ exists and is continuous
- γ is space-filling.

Let's do this part by part.

- We know γ_n are continuous, so to prove γ is continuous we only need to construct uniform continuity, but we don't know the limit, so instead we construct uniform Cauchy which is equivalent.

Fix $t \in [0, 1]$. For any $n \in \mathbb{N}$,

$$\begin{aligned} \exists m_1, \dots, m_n \in \{0, 1, 2, 3\} : t \in & \left[0.m_1\dots m_{n+1}, 0.m_1\dots m_{n+1} + \frac{1}{4^{n+1}} \right] \\ & \subset \left[0.m_1\dots m_n, 0.m_1\dots m_n + \frac{1}{4^n} \right]. \end{aligned}$$

Since clearly

$$0.m_1 \dots m_{n+1} \geq 0.m_1 \dots m_n$$

and

$$0.m_1 \dots m_{n+1} + \frac{1}{4^{n+1}} \leq 0.m_1 \dots m_n + \frac{1}{4^{n+1}} + \frac{3}{4^{n+1}} = 0.m_1 \dots m_n + \frac{1}{4^n}.$$

This means $\gamma_n(t), \gamma_{n+1}(t) \in S_{0.m_1 \dots m_n}$. So $|\gamma_{n+1}(t) - \gamma_n(t)| \leq \frac{\sqrt{2}}{2^n}$, length of diagonal. So $\forall m, n \in \mathbb{N}, \forall t \in [0, 1]$, we have

$$\begin{aligned} |\gamma_{n+m}(t) - \gamma_n(t)| &\leq |\gamma_{n+m}(t) - \gamma_{n+m-1}(t)| + |\gamma_{n+m-1}(t) - \gamma_{n+m-2}(t)| + \\ &\quad \dots + |\gamma_{n+1}(t) - \gamma_n(t)| \\ &\leq \sqrt{2} (2^{-n-m+1} + 2^{-n-m} + \dots + 2^{-n+1}) \\ &\leq \sqrt{2} \cdot 2^{-n+1} \underbrace{\sum_{k=0}^{\infty} 2^{-k}}_{\text{geometric}=2} \rightarrow 0. \end{aligned}$$

as desired.

2. We now want $\forall p \in [0, 1]^2, \exists t_0 \in [0, 1] : \gamma(t_0) = p$. By construction, $\forall d > 0, \exists t \in [0, 1] : |\gamma(t) - p| < d$: how? Consider partition of $[0, 1]^2$ by 4^n squares of size $\frac{1}{2^n}$. Then $\forall \tau_n \in [0.m_1 \dots m_n, 0.m_1 \dots m_n + \frac{1}{4^n}]$, $\gamma_n(\tau_n) \in S_{0.m_1 \dots m_n}$. Choose $0.m_1 \dots m_n$ such that $S \in S_{0.m_1 \dots m_n}$. Then $|\gamma_n(\tau_n) - p| < \frac{\sqrt{2}}{2^n}$. So

$$|\gamma(\tau_n) - p| \leq |\gamma(\tau_n) - \gamma_n(\tau_n)| + |\gamma_n(\tau_n) - p| \leq \|\gamma - \gamma_n\|_{\infty} + \frac{\sqrt{2}}{2^n} \rightarrow 0.$$

Now set $d = \frac{1}{n}$, $n \in \mathbb{N}$. Then we are dealing with a sequence of time $(t_n) : \lim_{n \rightarrow \infty} \underbrace{|\gamma(t_n) - p|}_{\leq \frac{1}{n}} =$

0. Equivalently, $\lim_{n \rightarrow \infty} \gamma(t_n) = p$. But $(t_n)_{n \geq 1}$ doesn't have to converge. But! $(t_n) \subset [0, 1]$ which is bounded closed. So apply Bolzano-Weierstrass to get a subsequence t_{n_k} . Then $\lim_{k \rightarrow \infty} t_{n_k} = t_0 \in [0, 1]$. So

$$p = \lim_{k \rightarrow \infty} \gamma(t_{n_k}) \underbrace{=}_{\text{continuity}} \gamma\left(\lim_{k \rightarrow \infty} t_{n_k}\right) = \gamma(t_0).$$

Finally we ask: is γ bijective? It's actually not injective, since there is a dense set of points of self intersection: $\gamma(t_1) = \gamma(t_2)$ but $t_1 \neq t_2$.

Theorem 3.4.1 (Netto's). A bijection between two manifolds of different dimensions (hyper-cubes in \mathbb{R}^n) cannot be continuous.

3.4.3 Cantor function, aka Devil's staircase

Let $(f_n)_{n \geq 0}$ be a sequence of functions on $[0, 1]$. $f_0(x) := x$. Then

$$f_{n+1}(x) := \begin{cases} \frac{1}{2}f_n(3x) & 0 \leq x \leq \frac{1}{3} \\ \frac{1}{2} & \frac{1}{3} < x < \frac{2}{3} \\ \frac{1}{2} + \frac{1}{2}f_n(3x-2) & \frac{2}{3} \leq x \leq 1 \end{cases}$$

Observations:

- $f_n : [0, 1] \rightarrow [0, 1]$
- increasing
- $f_{n+1}(0) = \frac{1}{2}f_n(0) = \frac{1}{2}^2 f_{n-1}(0) = \dots = \frac{1}{2}^{n+1} f_0(0) = 0$
- $f_{n+1}(1) = \frac{1}{2} + \frac{1}{2}f_n(1) \underbrace{=}_{\text{induction}} \frac{1}{2} + \frac{1}{2} = 1$

Claims:

1. $f_n \in C[0, 1] \forall n \geq 0$.

Proof. Use induction. Obviously $f_0 \in C[0, 1]$. Now suppose f_n is continuous. Then f_{n+1} is continuous on $[0, \frac{1}{3}] \cup (\frac{1}{3}, \frac{2}{3}) \cup (\frac{2}{3}, 1]$ by construction. We then only need to check two points $x = \frac{1}{3}, \frac{2}{3}$.

We have

$$\lim_{x \uparrow \frac{1}{3}} f_{n+1}(x) = \lim_{x \uparrow \frac{1}{3}} \frac{1}{2} f_n(3x) = \frac{1}{2} \lim_{x \uparrow 1} f_n(x) = \frac{1}{2} f_n(1) = \frac{1}{2},$$

and similarly $\lim_{x \downarrow \frac{1}{3}} f_{n+1}(x) = \frac{1}{2}$. Two limits agree so continuous at $\frac{1}{3}$. Similarly it's continuous at $\frac{2}{3}$. \square

2. The sequence $(f_n) \in C[0, 1]$ is uniformly Cauchy. Therefore the limit $f := \lim_{n \rightarrow \infty} f_n$ is continuous on $[0, 1]$, which is defined as Cantor function.

Proof. We have

$$\begin{aligned}
\|f_{n+1} - f_n\|_\infty &\leq \max \left\{ \sup_{[0, \frac{1}{3}]} |f_{n+1}(x) - f_n(x)|, \underbrace{\sup_{[\frac{1}{3}, \frac{2}{3}]} |f_{n+1}(x) - f_n(x)|}_0, \sup_{[\frac{2}{3}, 1]} |f_{n+1}(x) - f_n(x)| \right\} \\
&= \max \left\{ \frac{1}{2} \sup_{[0, \frac{1}{3}]} |f_n(3x) - f_{n-1}(3x)|, \frac{1}{2} \sup_{[\frac{2}{3}, 1]} |f_n(3x) - f_{n-1}(3x)| \right\} \\
&= \max \left\{ \frac{1}{2} \sup_{[0, 1]} |f_n(x) - f_{n-1}(x)|, \frac{1}{2} \sup_{[0, 1]} |f_n(x) - f_{n-1}(x)| \right\} \\
&= \frac{1}{2} \sup_{[0, 1]} |f_n(x) - f_{n-1}(x)| \\
&= \frac{1}{2} \underbrace{\|f_n - f_{n-1}\|_\infty}_{\leq C}.
\end{aligned}$$

If we iterate this we have

$$\|f_{n+1} - f_n\|_\infty \leq \frac{1}{2} \|f_n - f_{n-1}\|_\infty \leq \frac{1}{2}^2 \|f_{n-1} - f_{n-2}\|_\infty \leq \cdots \leq \frac{1}{2}^n \|f_1 - f_0\|_\infty.$$

So $\forall n, m \in \mathbb{N}$,

$$\begin{aligned}
\|f_{n+m} - f_n\|_\infty &\leq \|f_{n+m} - f_{n+m-1}\|_\infty + \|f_{n+m-1} - f_{n+m-2}\|_\infty + \cdots + \|f_{n+1} - f_n\|_\infty \\
&\leq C \left(\frac{1}{2}^{n+m} + \frac{1}{2}^{n+m-1} + \cdots + \frac{1}{2}^{n+1} \right) \\
&\leq \frac{1}{2}^{n+1} C \underbrace{\sum_{k=1}^{\infty} \frac{1}{2}^k}_{\text{geometric}} \rightarrow 0.
\end{aligned}$$

□

Properties of Cantor function:

1. $f : [0, 1] \rightarrow [0, 1]$ is continuous, monotonically increasing and $f(0) = 0$, $f(1) = 1$. By IVT f is surjective. Also by Theorem 1.1.15 it's integrable.
2. Take $\lim_{n \rightarrow \infty} f_n$ we have

$$f(x) := \begin{cases} \frac{1}{2} f(3x) & 0 \leq x \leq \frac{1}{3} \\ \frac{1}{2} & \frac{1}{3} < x < \frac{2}{3} \\ \frac{1}{2} + \frac{1}{2} f(3x - 2) & \frac{2}{3} \leq x \leq 1 \end{cases},$$

a functional equation for f . Therefore

$$\int_0^{\frac{1}{3}} f(x) \, dx = \frac{1}{2} \int_0^{\frac{1}{3}} f(3x) \, dx = \frac{1}{6} \int_0^1 f(x) \, dx$$

and

$$\int_{\frac{2}{3}}^1 f(x) \, dx = \frac{1}{6} + \frac{1}{2} \int_{\frac{2}{3}}^1 f(3x-2) \, dx = \frac{1}{6} + \frac{1}{6} \int_0^1 f(x) \, dx$$

so

$$\frac{1}{6} \int_0^1 f + \frac{1}{2} \times \frac{1}{3} + \frac{1}{6} + \frac{1}{6} \int_0^1 f = \int_0^1 f,$$

hence $\int_0^1 f = \frac{1}{2}$.

3. We know f is constant on $E_0 = (\frac{1}{3}, \frac{2}{3})$. Obviously it's also constant on $E_{1,1} = \frac{1}{3}E_0$, $E_{1,2} = \frac{2}{3} + \frac{1}{3}E_0$, and $f|_{E_{1,1}} = \frac{1}{4}$, $f|_{E_{1,2}} = \frac{3}{4}$. Moreover they do not overlap since f is continuous. Note $|E_0| = \frac{1}{3}$, $|E_{1,1}| = |E_{1,2}| = \frac{1}{9}$.

More generally, if $f|_E$ is constant, then it's also constant on $\frac{1}{3}E$, $\frac{2}{3} + \frac{1}{3}E$. We iterate this and after k steps we have

$$E_0, E_{1,1}, E_{1,2}, E_{2,1}, E_{2,2}, E_{2,3}, E_{2,4}, \dots, E_{k,1}, \dots, E_{k,2^k},$$

a total of $2^{k+1} - 1$ intervals of length $\frac{1}{3}, \frac{1}{3^2}, \dots, \frac{1}{3^{k+1}}$, on which the value of f are

$$\frac{m}{2^{k+1}}, \quad 1 \leq m \leq 2^{k+1} - 1,$$

i.e. distinct. Therefore they are disjoint. The miracle here is that the total length of these intervals is

$$\frac{1}{3} + 2\frac{1}{3^2} + 4\frac{1}{3^3} + \dots = \sum_{k=0}^{\infty} \frac{1}{3} \cdot \frac{2^k}{3} = \frac{\frac{1}{3}}{1 - \frac{2}{3}} = 1.$$

The set $C := [0, 1] \setminus E$ is called Cantor set. Its total length is zero, yet $f : C \rightarrow [0, 1]$ is a surjectivity: a standard example in measure theory, fractal geometry, analysis, ...

Remark. Please take a look at the exercises at the end of week 6 notes, giving a more analytic characteristic of Cantor set and a formula for Cantor function.

4 Complex analysis

4.1 Review of complex numbers

$\mathbb{C} = \{x + iy, \, x, y \in \mathbb{R}\}$ where $i^2 = -1$. This gives a field of complex numbers, in other words you can multiply and divide (nonzero denominators).

Notation (Conjugate). $\bar{z} := x - iy$

Notation (Modulus). $|z| := \sqrt{x^2 + y^2}$

Recall these properties:

1. $\bar{\bar{z}} = z$
2. $\overline{z + w} = \bar{z} + \bar{w}$
3. $\overline{zw} = \bar{z}\bar{w}$
4. $z\bar{z} = |z|^2$ and $|z| = |\bar{z}|$

Note there is an isomorphism between $\mathbb{R}^2 \cong \mathbb{C}$: $\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} \Re z \\ \Im z \end{pmatrix}$. This is norm preserving: $|z| = \left\| \begin{pmatrix} x \\ y \end{pmatrix} \right\|_{\mathbb{R}^2}$ (Euclidean norm).

4.2 Introduction

Definition 4.2.1. $(z_n)_{n \in \mathbb{N}} \subset \mathbb{C}$ converges to $z_0 \in \mathbb{C}$ if

$$\forall \varepsilon > 0, \exists N_\varepsilon : n > N_\varepsilon \Rightarrow |z_n - z_0| < \varepsilon.$$

Equivalently, $\lim_{n \rightarrow \infty} |z_n - z_0| = 0$.

Definition 4.2.2. $\Omega \subset \mathbb{C}$ is *open* if

$$\forall z \in \Omega, \exists r > 0 : \mathbb{B}_r(z) = \{w \in \mathbb{C} : |w - z| < r\} \subset \Omega.$$

where \mathbb{B} is called an *open ball* (which is open).

Definition 4.2.3. $\Omega \subset \mathbb{C}$ is *closed* if $\Omega^C := \mathbb{C} \setminus \Omega$ is open.

Notation (Closed ball). $\bar{\mathbb{B}}_r(z) = \{w \in \mathbb{C} : |w - z| \leq r\}$

Definition 4.2.4. $K \subset \mathbb{C}$ is sequentially compact if for any $(z_k)_{k \in \mathbb{N}} \subset K$ there is a subsequence converging in K . (Sequentially compact \Leftrightarrow closed and bounded)

Definition 4.2.5. A \mathbb{C} -valued function on \mathbb{C} is a map $f : \mathbb{C} \rightarrow \mathbb{C}$ which can be written as $z = x + iy \mapsto f(z) = u(x, y) + iv(x, y)$.

So f can be thought as a function $\mathbb{R}^2 \rightarrow \mathbb{R}^2$, $\begin{pmatrix} x \\ y \end{pmatrix} \mapsto \begin{pmatrix} u(x, y) \\ v(x, y) \end{pmatrix}$.

Definition 4.2.6. $f : \Omega \subset \mathbb{C} \rightarrow \mathbb{C}$ is continuous at $z_0 \in \Omega$ if

$$\forall \varepsilon > 0, \exists \delta > 0 : (z \in \Omega, |z - z_0| < \delta) \Rightarrow |f(z) - f(z_0)| < \varepsilon.$$

Equivalently, $\lim_{z \rightarrow z_0} f(z) = f(z_0)$.

Definition 4.2.7. $f : \underbrace{\Omega}_{\text{unless state otherwise this is open}} \rightarrow \mathbb{C}$ is *complex differentiable* at $z \in \Omega$ if

$$\lim_{h \rightarrow 0} \frac{f(z+h) - f(z)}{h}$$

where $h \in \mathbb{C}$ exists. In this case the limit is called the (*complex*) *derivative*, denoted $f'(z)$.

Recall in context of multivariable real functions, $f : \mathbb{R}^n \rightarrow \mathbb{R}^k$ is differentiable at $p \in \mathbb{R}^n$ if $\exists Df(p) \in \mathcal{L}(\mathbb{R}^n, \mathbb{R}^k)$:

$$\lim_{h \rightarrow 0} \frac{\|f(p+h) - f(p) - Df(p)h\|_k}{\|h\|_n} = 0$$

We cannot divide by h as \mathbb{R}^n is not a field, but \mathbb{C} is a field, so formula in Definition 1.1.13 is well-defined, albeit it looks more like a definition of $\frac{\partial f}{\partial x}$. Hence it must exist along any curve passing through zero. This means we can derive the simplest necessary condition for existence of complex derivative:

$$\lim_{\Delta x \rightarrow 0} \lim_{\Delta y \rightarrow 0} \frac{f(z+h) - f(z)}{h} = \lim_{\Delta y \rightarrow 0} \lim_{\Delta x \rightarrow 0} \frac{f(z+h) - f(z)}{h}$$

where $h = \Delta x + i\Delta y$.

Let $f(z) = u(x, y) + iv(x, y)$. Then

$$\begin{aligned} \lim_{\Delta x \rightarrow 0} \frac{f(z + \Delta x) - f(z)}{\Delta x} &= \lim_{\Delta y \rightarrow 0} \frac{f(z + i\Delta y) - f(z)}{i\Delta y} \\ &= \lim_{\Delta x \rightarrow 0} \frac{(u(x + \Delta x, y) - u(x, y)) + i(v(x + \Delta x, y) - v(x, y))}{\Delta x} \\ &= \lim_{\Delta y \rightarrow 0} \frac{u(x, y + \Delta y) - u(x, y) + i(v(x, y + \Delta y) - v(x, y))}{i\Delta y} \end{aligned}$$

so if we denote partial derivative of $u : \mathbb{R}^2 \rightarrow \mathbb{R}$ with respect to x , we can write

$$\frac{\partial u}{\partial x}(x, y) + i \frac{\partial v}{\partial x}(x, y) = \frac{1}{i} \left(\frac{\partial u}{\partial y}(x, y) + i \frac{\partial v}{\partial y}(x, y) \right),$$

i.e.

$$\begin{cases} \frac{\partial u}{\partial x}(x, y) = \frac{\partial v}{\partial y}(x, y) \\ \frac{\partial v}{\partial x}(x, y) = -\frac{\partial u}{\partial y}(x, y) \end{cases}$$

This is called Cauchy–Riemann equations.

Example 4.2.8. 1. $f(z) = z$, $z \in \mathbb{C}$, the identity map. Then $\forall z \in \mathbb{C}$,

$$\lim_{h \rightarrow 0} \frac{f(z+h) - f(z)}{h} = \lim_{h \rightarrow 0} \frac{z+h-z}{h} = 1.$$

So $f'(z) = 1$.

2. $g(z) = \bar{z}$, $z \in \mathbb{C}$, conjugation of identity map. Then

$$\lim_{h \rightarrow 0} \frac{g(z+h) - g(z)}{h} = \lim_{h \rightarrow 0} \frac{\bar{h}}{h}$$

which we claim does not exist. Take $h = \rho e^{i\phi}$, then $\frac{\bar{h}}{h} = e^{-2i\phi}$ depends on angle of approach.

It's also reasonable to check if Cauchy–Riemann can verify of this non-differentiability. We write $g = u + iv$ where $u(x, y) = x$ and $v(x, y) = -y$. Then $u_x = 1 \neq v_y = -1$.

Remark. However, as a function on $\mathbb{R}^2 \rightarrow \mathbb{R}^2$, $\begin{pmatrix} x \\ y \end{pmatrix} \mapsto \begin{pmatrix} x \\ -y \end{pmatrix}$ is differentiable by existence and continuity of its partial derivatives.

Remark. [Demystification]

- If $f'(z) := \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h}$ exists then clearly f is continuous at z .
- Let $h(\Delta x) := \begin{pmatrix} \Delta x \\ 0 \end{pmatrix}$ where $\Delta x \rightarrow 0$. Notice that

$$f'(z) = \lim_{\Delta x \rightarrow 0} \frac{f(z + h\Delta x) - f(z)}{h\Delta x}$$

is just the partial derivative $u_x(x, y) + iv_x(x, y)$ which by linearity is just $\frac{\partial}{\partial x} f(z)$. By similar argument we conclude that if $f'(z)$ exists then it equals both partial derivatives $\frac{\partial}{\partial x} f(z)$ and $\frac{1}{i} \frac{\partial}{\partial y} f(z)$.

- $(z^n)' = nz^{n-1}$

Definition 4.2.9. $f : \Omega \subset \mathbb{C} \rightarrow \mathbb{C}$ is *analytic* or *holomorphic* at $z \in \Omega$ if $\exists U \in \Omega$, an open neighbourhood of z where f is complex differentiable at its every point.

f is analytic in $\Omega \subset \mathbb{C}$ if it is differentiable at every point of Ω .

Definition 4.2.10. $f : \mathbb{C} \rightarrow \mathbb{C}$ is *entire* if it is analytic at every $z \in \mathbb{C}$.

Remark. We can think of U as $\mathbb{B}_r(z)$ for some $r > 0$.

Why do we need these definitions?

Example 4.2.11 (Functions complex differentiable at one point but not analytic). Consider $f : z \mapsto |z|^2$. It's differentiable at 0 since

$$\lim_{h \rightarrow 0} \frac{h \cdot h}{h} = 0.$$

But if we write $f = u + iv$ then $u = x^2 + y^2$, $v = 0$. So $u_x = 2x$, $v_y = 0$, $u_y = 2y$, $v_x = 0$, i.e. Cauchy–Riemann is only satisfied when $x = y = 0$. Therefore f is not analytic at $z = 0$.

We have the knowledge of previous Remark. But actually Cauchy–Riemann gives us something more.

4.3 Algebraic meaning of Cauchy–Riemann

Consider $z, \bar{z} : \mathbb{R}^2 \rightarrow \mathbb{R}$, $z = x + iy$ and $\bar{z} = x - iy$. Then

$$x = \frac{z + \bar{z}}{2}, \quad y = \frac{z - \bar{z}}{2}.$$

By chain rule,

$$\frac{\partial}{\partial \bar{z}} = \frac{\partial x}{\partial \bar{z}} \frac{\partial}{\partial x} + \frac{\partial y}{\partial \bar{z}} \frac{\partial}{\partial y} = \frac{1}{2} \frac{\partial}{\partial x} - \frac{i}{2} \frac{\partial}{\partial y}.$$

Suppose f is differentiable at z . Then by Cauchy–Riemann

$$\frac{\partial}{\partial \bar{z}} f(z, \bar{z}) = \frac{1}{2}(u_x + iv_x) + \frac{i}{2}(u_y + iv_y) = \frac{1}{2}(u_x - v_y) + \frac{i}{2}(u_y + v_x) = 0.$$

i.e. f doesn't depend on \bar{z} , so we can simply write $f(z)$ (which we are interested in) instead of $f(z, \bar{z})$.

Soon we will find out that the reverse is also true: complex differentiability \Leftrightarrow differentiability in $\mathbb{R}^2 +$ Cauchy–Riemann (or lack of dependence on \bar{z}).

Let $\phi : \mathbb{C} \rightarrow \mathcal{M}_2(\mathbb{R})$, $z = (a + ib) \mapsto \begin{pmatrix} a & -b \\ b & a \end{pmatrix}$. It's an injection, and $\phi : \mathbb{C} \rightarrow \text{Im } \phi$ is of course then a bijection. But it's also an isomorphism:

$$\phi(z_1 + z_2) = \begin{pmatrix} x_1 + x_2 & -y_1 - y_2 \\ y_1 + y_2 & x_1 + x_2 \end{pmatrix} = \begin{pmatrix} x_1 & -y_1 \\ y_1 & x_1 \end{pmatrix} + \begin{pmatrix} x_2 & -y_2 \\ y_2 & x_2 \end{pmatrix} = \phi(z_1) + \phi(z_2)$$

and

$$\phi(z_1 z_2) = \begin{pmatrix} x_1 x_2 - y_1 y_2 & -x_1 y_2 - y_1 x_2 \\ x_1 y_2 + y_1 x_2 & x_1 x_2 - y_1 y_2 \end{pmatrix} = \begin{pmatrix} x_1 & -y_1 \\ y_1 & x_1 \end{pmatrix} \begin{pmatrix} x_2 & -y_2 \\ y_2 & x_2 \end{pmatrix} = \phi(z_1) \phi(z_2).$$

Let $\psi : \mathbb{C} \rightarrow \mathbb{R}^2$, $x + iy \mapsto \begin{pmatrix} x \\ y \end{pmatrix}$ which is norm preserving: $|z| = |\psi(z)|_{\mathbb{R}^2}$. Note that it respects ϕ :

$$\psi(z_1 z_2) = \begin{pmatrix} x_1 x_2 - y_1 y_2 \\ x_1 y_2 + y_1 x_2 \end{pmatrix} = \phi(z_1) \psi(z_2) = \begin{pmatrix} x_1 & -y_1 \\ y_1 & x_1 \end{pmatrix} \begin{pmatrix} x_2 \\ y_2 \end{pmatrix},$$

so it's an isomorphism between modules \mathbb{C}, \mathbb{R}^2 .

Theorem 4.3.1. $f : \Omega \rightarrow \mathbb{C}$ is complex differentiable at $z \in \Omega$ if and only if it is differentiable at $(\Re z, \Im z)$ as a function $\Omega \subset \mathbb{R}^2 \rightarrow \mathbb{R}$ and its partial derivatives satisfy Cauchy–Riemann.

Proof. \Rightarrow : Suppose

$$\lim_{h \rightarrow 0} \left| \frac{f(z+h) - f(z) - f'(z)h}{h} \right| = 0.$$

By norm-preserving of ψ we have

$$\lim_{h \rightarrow 0} \frac{|\psi(f(z+h) - f(z) - f'(z)h)|}{|\psi(h)|} = 0.$$

so

$$\lim_{h \rightarrow 0} \frac{|\psi f(z+h) - \psi f(z) - \psi(f'(z)h)|}{|\psi(h)|} = 0.$$

where $\psi(f'(z)h) = \phi(f'(z)) \cdot \psi(h)$ as we've seen. This means ψf is differentiable at $\psi(z) = \begin{pmatrix} \Re z \\ \Im z \end{pmatrix}$ with derivative $\phi(f'(z))$. Satisfaction of Cauchy–Riemann was previously checked.

\Leftarrow : Suppose $\psi f = \begin{pmatrix} u \\ v \end{pmatrix}$ is differentiable at $\begin{pmatrix} x \\ y \end{pmatrix} = \psi(z)$. We can write

$$\lim_{h \rightarrow 0} \frac{|\psi f(z+h) - \psi f(z) - D\psi f(z) \cdot \psi(h)|_{\mathbb{R}^2}}{|\psi(h)|_{\mathbb{R}^2}}$$

where

$$\begin{aligned} D\psi f(z) &= \begin{pmatrix} u_x & u_y \\ v_x & v_y \end{pmatrix} && \text{the Jacobian (seen in MA259)} \\ &= \begin{pmatrix} u_x & -v_x \\ v_x & u_x \end{pmatrix} && \text{by Cauchy-Riemann} \\ &= \phi(u_x + iv_x) && \text{by definition} \\ &= \phi(f_x) \end{aligned}$$

So by norm-preserving of ψ and $\phi(f_x(z))\psi(h) = \psi(f_x(z) \cdot h)$ we can write

$$\lim_{h \rightarrow 0} \left| \frac{f(z+h) - f(z) - f_x(z)h}{h} \right| = 0,$$

i.e. f is complex differentiable at z and $f'(z) = f_x(z) = \frac{\partial}{\partial z} f(z)$.

□

Theorem 4.3.2. Let $f, g : \Omega \rightarrow \mathbb{C}$ be analytic. Then

- $(fg)' = f'g + fg'$
- $\left(\frac{f}{g}\right)' = \frac{f'g - fg'}{g^2}$ ($g \neq 0$)
- $(f(g))' = f'(g) \cdot g'$ ($\text{Im } g \subset \Omega$)

Example 4.3.3. $f : z \rightarrow z^n$ on \mathbb{C} , $n \in \mathbb{N}_0$. f is entire and $f'(z) = nz^{n-1}$. We can see this since $(x, y) \mapsto (x + iy)^n$ is a polynomial with respect to x, y , which is differentiable, and

$$\frac{\partial}{\partial \bar{z}} z^n = nz^{n-1} \frac{\partial \bar{z}}{\partial z} = nz^{n-1} \left(\frac{1}{2} \times 1 - \frac{i}{2} \times (-i) \right) = nz^{n-1} \times 0 = 0.$$

So Cauchy-Riemann is satisfied.

4.4 Power series

Definition 4.4.1. $(a_n) \subset \mathbb{C}$. $\sum_{n=0}^{\infty} a_n$ converges if $\left(\sum_{n=0}^k a_n\right)$ converges in \mathbb{C} .

Definition 4.4.2. $\sum_{n=0}^{\infty} a_n$ converges absolutely if $\sum_{k=0}^{\infty} |a_n| = \sum_{k=0}^{\infty} \sqrt{a_n \bar{a}_n}$ converges.

Theorem 4.4.3 (Root test).

$$\limsup_{n \rightarrow \infty} |a_n|^{\frac{1}{n}} \begin{cases} > 1 \Rightarrow \sum_n a_n \text{ diverges} \\ < 1 \Rightarrow \sum_n a_n \text{ converges (absolutely)} \end{cases}$$

Theorem 4.4.4 (Ratio test). $(a_n) \subset \mathbb{C}$ and $a_n \neq 0$ eventually. Then

- $\limsup_{n \rightarrow \infty} \left| \frac{a_{n+1}}{a_n} \right| < 1 \Rightarrow \sum_n a_n$ converges (absolutely)
- $\left| \frac{a_{n+1}}{a_n} \right| \geq 1$ eventually $\Rightarrow \sum_n a_n$ diverges
- If $L := \lim_{n \rightarrow \infty} \frac{|a_{n+1}|}{|a_n|}$ exists then $L > 1 \Rightarrow$ divergence, $L < 1 \Rightarrow$ convergence

Remark. Above 2 theorems are proved using comparison with geometric series

$$\sum_{k=0}^{\infty} z^k = \begin{cases} \frac{1}{1-z} & |z| < 1 \\ \text{divergence} & |z| > 1 \end{cases} \quad z \in \mathbb{C}$$

Theorem 4.4.5. Given $(a_n) \subset \mathbb{C}$, then $\exists R \in [0, \infty] : \sum_{k=0}^{\infty} a_k z^k$ converges $\forall z$ when $|z| < R$ and diverges $\forall z$ when $|z| > R$. R is called the *radius of convergence*, and

$$R = \frac{1}{\limsup_{n \rightarrow \infty} |a_n|^{\frac{1}{n}}},$$

and we assert $R = \infty$ when $\limsup_{n \rightarrow \infty} |a_n|^{\frac{1}{n}} = 0$.

Proof. This formula is directly from applying the root test to $\sum_{n=0}^{\infty} a_n z^n$. By linearity of \limsup we write

$$\limsup_{n \rightarrow \infty} |a_n z^n|^{\frac{1}{n}} = |z| \limsup_{n \rightarrow \infty} |a_n|^{\frac{1}{n}} \begin{cases} > 1 \Rightarrow \sum_n a_n \text{ diverges} \\ < 1 \Rightarrow \sum_n a_n \text{ converges (absolutely)} \end{cases}$$

then if we denote R as stated in the theorem we have desired result. \square

Theorem 4.4.6. Let $R > 0$ be the radius of convergence of $\sum_{n=0}^{\infty} a_n z^n$. Then $\forall 0 < r < R$, $\sum_{n=0}^{\infty} a_n z^n$ converges uniformly with respect to z on $\overline{\mathbb{B}}_r(0)$.

Proof. Exercise. (Identical to the real case.) \square

Theorem 4.4.7. Let $\sum_{n=0}^{\infty} a_n z^n$ have the radius of convergence $R > 0$. Then $z \mapsto \sum_{n=0}^{\infty} a_n z^n$ is analytic in $\mathbb{B}_R(0)$. Moreover,

$$\left(\sum_{n=0}^{\infty} a_n z^n \right)' = \sum_{n=1}^{\infty} n a_n z^{n-1}, \quad |z| < R.$$

Proof. We know $(z^n)' = nz^{n-1}$. Consider $\sum_{n=1}^{\infty} na_n z^{n-1}$. Then

$$\limsup_{n \rightarrow \infty} |na_n|^{\frac{1}{n}} = \limsup_{n \rightarrow \infty} \underbrace{n^{\frac{1}{n}}}_{\rightarrow 1: n^{\frac{1}{n}} = e^{\frac{1}{n} \log n}} |a_n|^{\frac{1}{n}} = \limsup_{n \rightarrow \infty} |a_n|^{\frac{1}{n}},$$

i.e. the two series on two sides of statement share the same radius of convergence R . We can therefore say $\sum_{n=0}^{\infty} a_n z^n$ converges pointwise and $\sum_{n=1}^{\infty} na_n z^{n-1}$ converges uniformly on $\mathbb{B}_R(0)$: the condition for interchange of limit and derivative, i.e. termwise differentiability (Theorem 3.2.10):

$$\left(\sum_{n=0}^{\infty} a_n z^n \right)' = \sum_{n=0}^{\infty} (a_n z^n)' = \sum_{n=1}^{\infty} na_n z^{n-1}.$$

□

Remark. This proof requires formulation of complex integral which will be introduced later. If you are not convinced without this definition, see typewritten notes for a “manual” proof.

Corollary 4.4.8. Let $\sum_{n=0}^{\infty} a_n z^n$ have the radius of convergence $R > 0$. Then $f : z \mapsto \sum_{n=0}^{\infty} a_n z^n$ is ∞ complex differentiable on $\mathbb{B}_R(0)$ and

$$f^{(k)}(0) = a_k k!$$

Proof. Iteration of above theorem gives

$$\begin{aligned} f'(z) &= \sum_{n=1}^{\infty} na_n z^{n-1} \\ f''(z) &= \sum_{n=2}^{\infty} n(n-1)a_n z^{n-2} \\ &\vdots \\ f^{(k)}(z) &= \sum_{n=k}^{\infty} n(n-1)\cdots(n-k+1) \underbrace{a_n z^{n-k}}_{a_k} \end{aligned}$$

so

$$f^{(k)}(0) = k(k-1)\cdots 1 \cdot a_k = k!a_k.$$

□

4.4.1 Exponential and circular functions

Definition 4.4.9. For $z \in \mathbb{C}$,

$$\begin{aligned} e^z &:= \sum_{n=0}^{\infty} \frac{z^n}{n!} \\ \cos z &:= \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} z^{2n} \\ \sin z &:= \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!} z^{2n+1} \\ \cosh z &:= \sum_{n=0}^{\infty} \frac{z^{2n}}{(2n)!} \\ \sinh z &:= \sum_{n=0}^{\infty} \frac{z^{2n+1}}{(2n+1)!} \end{aligned}$$

Using ratio test we can see $R = \infty$ for all of above.

Example 4.4.10.

$$(e^z)' = \left(\sum_{n=0}^{\infty} \frac{z^n}{n!} \right)' = \sum_{n=0}^{\infty} \frac{(z^n)'}{n!} = \sum_{n=1}^{\infty} \frac{1}{(n-1)!} z^{n-1} = \sum_{n=0}^{\infty} \frac{z^n}{n!} = e^z.$$

Proposition 4.4.11.

$$\begin{aligned} \cos z &= \frac{e^{iz} + e^{-iz}}{2} \\ \sin z &= \frac{e^{iz} - e^{-iz}}{2i} \\ \cosh z &= \frac{e^z + e^{-z}}{2} \\ \sinh z &= \frac{e^z - e^{-z}}{2} \end{aligned}$$

Proof.

$$\begin{aligned} \frac{e^{iz} + e^{-iz}}{2} &= \frac{1}{2} \sum_{n=0}^{\infty} \frac{1}{n!} ((iz)^n + (-iz)^n) = \sum_{n=0}^{\infty} \frac{1}{n!} \underbrace{\frac{1 + (-1)^n}{2}}_{\substack{0 \text{ when } n \text{ is odd} \\ 1 \text{ when } n \text{ is even}}} (iz)^n \\ &= \sum_{n=2k}^{\infty} \frac{1}{(2k)!} (iz)^{2k} = \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k)!} z^{2k} =: \cos z \end{aligned}$$

Proofs of remaining statements are left as an exercise. □

Note for $x \in \mathbb{R}$, plots of $\cos x$ and $\cosh x$ look very different:

But in the complex plane, cosh is just a composition of cos and its $\frac{\pi}{2}$ rotation, i.e. $\cosh z = \cos iz$ and similarly $\sinh z = \sin iz$.

Theorem 4.4.12 (Properties of exponential).

1. $e^{z+w} = e^z e^w \quad \forall z, w \in \mathbb{C}$
2. $e^z \neq 0 \quad \forall z \in \mathbb{C}$
3. $e^z = 1 \Leftrightarrow z = 2k\pi i, k \in \mathbb{Z}$
4. $e^z = -1 \Leftrightarrow z = (2k+1)\pi i, k \in \mathbb{Z}$

4.5 Argument and Log

We can write z as $|z|e^{i\theta}$. Let $z_1 z_2 \neq 0$, then

$$z_1 = z_2 \Leftrightarrow |z_1|e^{i\theta_1} = |z_2|e^{i\theta_2} \Leftrightarrow \begin{cases} |z_1| = |z_2| \\ \theta_1 - \theta_2 = 2\pi k, k \in \mathbb{Z} \end{cases}$$

So we define the function $\arg : \mathbb{C} \setminus \{0\} \rightarrow \{\text{subsets of } \mathbb{R}\}$ by

$$z \mapsto \{\theta + 2\pi k, k \in \mathbb{Z}\}.$$

Note that \arg is a *multivalued* or *set-valued* function.

Proposition 4.5.1 (Properties of argument). 1. $\arg(\alpha z) = \arg(z)$ for $\alpha > 0$

2. $\arg(\alpha z) = \pi + \arg(z)$ for $\alpha < 0$

- To see this note that $\alpha = (-\alpha)(-1) = |\alpha|e^{i\pi}$

3. $\arg\left(\frac{1}{z}\right) = -\arg(z)$
4. $\arg(\bar{z}) = -\arg(z)$
5. $\arg(zw) = \arg(z) + \arg(w)$

We can see there's much unnecessary ambiguity of \arg , so we define a single valued function related to it, called principal argument:

$$\text{Arg}(z) = (-\pi, \pi] \cap \arg(z)$$

Note that Arg is not analytic in $\mathbb{C} \setminus \{0\}$:

$$\lim_{\varepsilon \downarrow 0} \text{Arg}(e^{i(\pi-\varepsilon)}) = \pi$$

$$\lim_{\varepsilon \downarrow 0} \text{Arg}(e^{i(\pi+\varepsilon)}) = -\pi,$$

but

$$\lim_{\varepsilon \downarrow 0} |e^{i(\pi-\varepsilon)} - e^{i(\pi+\varepsilon)}| = 0.$$

Now we would like to find $w : e^w = z$. We know

$$e^w = |z|e^{i\theta} = e^{\log|z| + i\arg(z)},$$

so define $\log : \mathbb{C} \setminus \{0\} \rightarrow \{\text{subsets of } \mathbb{C}\}$ by $z \mapsto \log z = \text{Log}|z| + i\arg(z)$ where Log is logarithm of \mathbb{R}^+ . Similar to \arg , we have a single value version $z \mapsto \text{Log}(z) = \text{Log}|z| + i\text{Arg}(z)$.

Unfortunately we have a clash of notations of real logarithm and complex principal logarithm.

Proposition 4.5.2 (Properties of logarithm). 1. $\log(zw) = \log z + \log w$

2. $\log z^{-1} = -\log z$

Similarly Log is not analytic in $\mathbb{C} \setminus \{0\}$: for any $x < 0$,

$$\lim_{\varepsilon \downarrow 0} \text{Log}(x + i\varepsilon) = \log|x| + i\pi$$

$$\lim_{\varepsilon \downarrow 0} \text{Log}(x - i\varepsilon) = \log|x| - i\pi,$$

so it's not continuous at $\{x < 0\}$.

But we see that Log is analytic on $\mathbb{C} \setminus \{x \leq 0\}$ by checking Cauchy–Riemann equations. (This is called a “branch cut”.) Now we can apply calculus:

$$e^{\text{Log} z} = z$$

$$(e^{\text{Log} z})' = z' = 1 = (\text{Log} z)' e^{\text{Log} z} = (\text{Log} z)' z$$

so $(\text{Log} z)' = \frac{1}{z}$.

If $\alpha \in \mathbb{C}$, $z \neq 0$, we define

$$z^\alpha := e^{\alpha \log z} = e^{\alpha \log |z| + \alpha i \arg(z)}$$

which is set-valued. If $\alpha \in \mathbb{Z}$ then $z \mapsto z^\alpha$ is single-valued:

$$e^{i\alpha \arg(z)} = e^{i(\alpha\theta + 2\pi \underbrace{k\alpha}_{\in \mathbb{Z}}), k \in \mathbb{Z}} = e^{i\alpha\theta},$$

and if $\alpha = \pm \frac{p}{q}$, $p, q \in \mathbb{N}$, then z^α consists of at most q elements:

$$\left\{ e^{\alpha \text{Log}|z|} e^{2\pi i \alpha k} : 0 \leq k \leq q-1 \right\},$$

and in particular we have the q -th roots of unity

$$1^{\frac{1}{q}} = \left\{ e^{2\pi i \frac{k}{q}} : 0 \leq k \leq q-1 \right\}.$$

4.6 Complex integration, contour integrals

Definition 4.6.1. $f : [a, b] \rightarrow \mathbb{C}$ is *integrable* if $\Re f, \Im f : [a, b] \rightarrow \mathbb{R}$ are integrable. Then

$$\int_a^b f := \int_a^b \Re f + i \int_a^b \Im f \in \mathbb{C}.$$

Proposition 4.6.2 (Properties of complex integration). 1. Linearity: $\alpha, \beta \in \mathbb{C}$, $f, g : [a, b] \rightarrow \mathbb{C}$ integrable, then

$$\int_a^b (\alpha f + \beta g) = \alpha \int_a^b f + \beta \int_a^b g$$

2. Interchangeability of conjugation and integration:

$$\overline{\int_a^b f} = \int_a^b \bar{f}$$

3. Triangle inequality:

$$\left| \int_a^b f \right| \leq \int_a^b |f|$$

Check. 1. Let $\alpha = \mu + i\nu$, $f = u + iv$, then

$$\alpha f = (\mu u - \nu v) + i(\mu v + \nu u).$$

By definition and linearity of Riemann integral,

$$\begin{aligned} \int_a^b \alpha f &= \mu \int_a^b u - \nu \int_a^b v + i \left(\mu \int_a^b v + \nu \int_a^b u \right) \\ &= (\mu + i\nu) \int_a^b u + i(\mu + i\nu) \int_a^b v \\ &= (\mu + i\nu) \int_a^b (u + iv) \\ &= \alpha \int_a^b f. \end{aligned}$$

2. Left as an exercise.

3. We know

$$\int_a^b f = \left| \int_a^b f \right| e^{i\theta} \quad \text{for some } \theta \in \mathbb{R}.$$

So

$$\left| \int_a^b f \right| = e^{-i\theta} \int_a^b f = \int_a^b (e^{-i\theta} f).$$

Let $e^{-i\theta} f = u + iv$, then

$$\int_a^b (e^{-i\theta} f) = \int_a^b u + i \int_a^b v$$

but this is real, so $\int_a^b v = 0$. We can therefore use the triangle inequality for real and conclude that

$$\int_a^b u \leq \int_a^b |u| \leq \int_a^b \sqrt{u^2 + v^2} = \int_a^b |e^{-i\theta} f| = \int_a^b |f|.$$

□

A more important aim is to define integral for $f : \mathbb{C} \rightarrow \mathbb{C}$. Such functions can be viewed as vector fields on \mathbb{R}^2 , suggesting we can borrow the idea of line integral: $\int_{\Gamma} f \, dz$ where Γ is an oriented curve in \mathbb{C} . We need some terminology.

Notation. 1. $\gamma : [a, b] \rightarrow \mathbb{C}$ denotes a C^1 map called a *parameterised curve*.

2. $\Gamma = \gamma([a, b]) \subset \mathbb{C}$, this is an unparameterised curve, the equivalence class of maps from \mathbb{R} to \mathbb{C} : $\gamma_1 \sim \gamma_2$ if $\text{Im } \gamma_1 = \text{Im } \gamma_2$.

3. If Γ is oriented, then $-\Gamma$ coincides with Γ as a subset of \mathbb{C} , but has the opposite orientation

4. Shorthand:

$$\int_{\Gamma} f(z) \, dz = \int_{\Gamma} f \, dz = \int_{\Gamma} f.$$

We use $\int_{\gamma} f$ to emphasise parameterisation.

Remark. For orientation to make sense, it is sufficient for γ to be regular if $\gamma' \neq 0$ (you have tangent vector everywhere)

Definition 4.6.3. Let $\Gamma \subset \mathbb{C}$ be oriented and $\gamma : [a, b] \rightarrow \mathbb{C}$ its parameterisation. Define

$$\int_{\Gamma} f := \int_a^b f(\gamma(t)) \overbrace{\gamma'(t) \, dt}^{\text{“dr”}}.$$

If Γ is piecewise C^1 , i.e. $\Gamma = \bigcup \Gamma_i$ where Γ_i 's are almost disjoint, then

$$\int_{\Gamma} f := \sum_{k=1}^n \int_{\Gamma_k} f.$$

Standard properties of Riemann integrals like linearity and additivity hold.

Lemma 4.6.4 (Representation invariance). 1.

$$\int_{-\gamma} f = - \int_{\gamma} f$$

(If $\gamma : [a, b] \rightarrow \mathbb{C}$, then $-\gamma = \gamma(a + b - \cdot)$ (shift by $a + b$ then change sign))

2. If $\gamma : [a, b] \rightarrow \mathbb{C}$ and $\phi : [\tilde{a}, \tilde{b}] \rightarrow [a, b]$ is bijective, increasing and C^1 , then

$$\int_{\gamma} f = \int_{\gamma \circ \phi} f$$

(ϕ is an orient-preserving reparameterisation)

Remark. 1. By analogy with multivariable calculus we can define

$$\int_{\Gamma} |f| |dz| := \int_a^b |f(\gamma(t))| \cdot |\gamma'(t)| \, dt$$

Notice that if $f = 1$, and write $\gamma(t) = x(t) + iy(t)$, then the above integral is

$$\int_a^b \sqrt{x'^2(t) + y'^2(t)} \, dt$$

so it's just the Euclidean length of Γ . Hence

$$\begin{aligned} \left| \int_{\Gamma} f \, dz \right| &= \left| \int_a^b f(\gamma(t)) \gamma'(t) \, dt \right| \leq \int_a^b |f(\gamma(t))| \cdot |\gamma'(t)| \, dt \\ &\leq \sup_{z \in \Gamma} |f(z)| \int_a^b |\gamma'(t)| \, dt = \sup_{\Gamma} |f| \cdot \text{length of } \Gamma \end{aligned}$$

2. We can define

$$\int_{\Gamma} f \, d\bar{z} := \int_a^b f(\gamma(t)) \cdot \overline{\gamma'(t)} \, dt,$$

but we will be mostly interested in

$$\int_{\Gamma} f \, dz$$

where f is analytic in an open subset $\Omega \subset \mathbb{C}$ and $\Gamma \in \Omega$ is an oriented curve. If we start considering all the versions of integrals we have listed here, we would end up reproducing theory of line integrals over vector fields in \mathbb{R}^2 . So by looking at the integral above, we specify on a very special class of vector fields, and this speciality comes from analyticity.

Example 4.6.5. 1. Consider

$$\int_{\Gamma=\partial\mathbb{B}_R(0)} z^n \, dz, \quad n \in \mathbb{Z}$$

where $\partial\mathbb{B}_R(0)$ is circle of radius R , centred at origin and oriented counterclockwise. We parameterise it by

$$\gamma(t) = Re^{it}, \quad t \in [0, 2\pi].$$

Then by definition,

$$\begin{aligned} \int_{\Gamma} z^n \, dz &= \int_0^{2\pi} (Re^{it})^n \cdot iRe^{it} \, dt = iR^{n+1} \int_0^{2\pi} e^{i(n+1)t} \, dt \\ &= iR^{n+1} \underbrace{\int_0^{2\pi} (\cos(n+1)t + i \sin(n+1)t) \, dt}_{0 \text{ unless } n+1=0} \\ &= iR^{n+1} \delta_{n,-1} \int_0^{2\pi} 1 \, dt \\ &= 2\pi i \delta_{n,-1}, \end{aligned}$$

which doesn't depend on R !

2. From the above we can consider the exponential integrated on the same Γ ; by its uniform convergence we can swap integral and infinite sum:

$$\int_{\Gamma} e^z \, dz = \int_{\Gamma} \sum_{n=0}^{\infty} \frac{z^n}{n!} \, dz = \sum_{n=0}^{\infty} \frac{1}{n!} \int_{\Gamma} z^n \, dz = \sum_{n=0}^{\infty} \frac{1}{n!} 2\pi i \delta_{n,-1} = 0.$$

3. Consider

$$\int_{\Gamma} \frac{e^z}{z^{k+1}} \, dz, \quad k \in \mathbb{N}_0.$$

We rewrite

$$\begin{aligned} \int_{\Gamma} \sum_{n=0}^{\infty} \frac{1}{n!} z^{n-1-k} dz &= \sum_{n=0}^{\infty} \frac{1}{n!} \int_{\Gamma} z^{n-1-k} dz \\ &= \sum_{n=0}^{\infty} \frac{1}{n!} 2\pi i \delta_{n-1-k, -1} \\ &= 2\pi i \sum_{n=0}^{\infty} \frac{1}{n!} \delta_{n,k} = 2\pi i \frac{1}{k!}. \end{aligned}$$

Note that $\frac{1}{k!}$ is the k -th term of Taylor of exponential at 0. We are integrating by differentiating. Also, take $k = 0$, we are integrating $\frac{e^x}{x}$ whose antiderivative (called exponential integral, a special function) is not expressible. We now can do something beyond Fundamental theorem of calculus.

Example 4.6.6.

$$I_k = \int_{\partial \mathbb{B}_R(1+i)} z^k dz, \quad k \in \mathbb{N}_0, \quad R > 0.$$

We start with parameterising the circle by

$$\gamma = (1+i) + Re^{it}, \quad t \in [0, 2\pi],$$

so by definition

$$\begin{aligned} I_k &= \int_0^{2\pi} \underbrace{(1+i+Re^{it})^k}_{z(\gamma)} \underbrace{iRe^{it}}_{\gamma'(t)} dt \\ &= \int_{\partial \mathbb{B}_R(0)} (1+i+w)^k dw \quad \text{change of variables} \\ &= \sum_{n=0}^k \binom{k}{n} (1+i)^{k-n} \int_{\partial \mathbb{B}_R(0)} w^n dw = 0. \quad \text{by binomial and previous example} \end{aligned}$$

Theorem 4.6.7 (Complex FTC, or line integrals of conservative fields). Let $F : \Omega \rightarrow \mathbb{C}$ be analytic such that $F' = f$ is continuous and $\gamma : [a, b] \rightarrow \Omega$ be an oriented C^1 curve in Ω . Then

$$\int_{\gamma} f dz = F(\gamma(b)) - F(\gamma(a)),$$

i.e. integral only depends on end points.

Proof.

$$\begin{aligned} \int_{\gamma} f dz &= \int_a^b f(\gamma(t)) \gamma'(t) dt = \int_a^b F'(\gamma(t)) \gamma'(t) dt \\ &= \int_a^b \frac{d}{dt} F(\gamma(t)) dt \quad \text{chain rule} \\ &= F(\gamma(b)) - F(\gamma(a)). \quad \text{usual FTC} \end{aligned}$$

□

Remark. Ω doesn't have to be simply connected.

4.6.1 Link with multivariable calculus

Let $r : [a, b] \rightarrow \mathbb{R}^2$ be a curve in \mathbb{R}^2 , $\underline{v} : \mathbb{R}^2 \rightarrow \mathbb{R}^2$ be a vector field. If $C = \text{Im } r$ is closed, then

$$\int_C \underline{v} \cdot d\mathbf{r} = \int_a^b \underline{v}(r(t)) \cdot r'(t) dt$$

is called the circulation of \underline{v} around C .

Now let $\Omega \subset \mathbb{R}^2$ be a regular domain (open, bounded, with piecewise C^1 boundary) which is positively oriented: meaning $N(t) = r'(t) \times e_z$ is outward normal. (We are thinking 2-d as a subspace of 3-d, e_z is the unit vector pointing from the board toward the viewers).

The most important particular case, from which we will build everything, is $\Omega = \partial\gamma$ where γ is simple closed curve oriented counterclockwise.

Explicitly, if $r'(t) = (x'(t), y'(t), 0)$ and $e_z = (0, 0, 1)$, then

$$N(t) = r'(t) \times e_z = (y'(t), -x'(t), 0). \quad (*)$$

If Ω is positively oriented in this sense, then flux of \underline{u} through $\partial\Omega$ is

$$\int_{\partial\Omega} \underline{u} \cdot N dt = \sum \int_{a_i}^{b_i} \underline{u}(\gamma(t)) N(t) dt$$

where the sum is over connect components of $\partial\Omega$.

Let $\Omega \subset \mathbb{R}^2$ be regular, positively oriented. Then

$$\int_{\Omega} \nabla \times \underline{u} \underbrace{dx dy}_{\text{area element}} = \int_{\partial\Omega} \underline{u} \cdot d\mathbf{r}$$

(Green's theorem) and similarly

$$\int_{\Omega} \nabla \cdot \underline{u} dx dy = \int_{\partial\Omega} \underline{u} \cdot N dt$$

(Divergence/Gauss's theorem).

Remark. $f := u + iv : \Omega \rightarrow \mathbb{C}$. Let $\gamma : [a, b] \rightarrow \Omega$ be a curve. Consider

$$\begin{aligned} \int_{\gamma} f dz &= \int_a^b (u + iv)(\gamma'_1 + i\gamma'_2) = \int_a^b (u\gamma'_1 - v\gamma'_2) + i \int_a^b (v\gamma'_1 + u\gamma'_2) \\ &= \int_a^b (u, -v) \cdot \underbrace{(\gamma'_1, \gamma'_2)}_{\gamma'(t)} + i \int_a^b (u, -v) \cdot \underbrace{(\gamma'_2, -\gamma'_1)}_{N(t)} \quad \text{by } (*) \text{ above} \\ &= \text{circulation of } \underline{f} + i \text{ flux of } \underline{f} \end{aligned}$$

where \underline{f} is a vector field built out of f which is written by $(u, -v) : \mathbb{R}^2 \rightarrow \mathbb{R}^2$.

Theorem 4.6.8 (Cauchy's). $\Omega \subset \mathbb{C}$ is open, simply connected. $f : \Omega \rightarrow \mathbb{C}$ is analytic, $\gamma \subset \Omega$ is a C^1 closed, simple curve (i.e. a contour). Then

$$\int_{\gamma} f dz = 0.$$

Proof. Let $D \subset \mathbb{C}$ be the domain bounded by γ (the interior of γ). D is then regular and $\partial D = \gamma$. D indeed exists by Jordan curve theorem. We claim $D \subset \Omega$. Indeed, suppose $D \not\subset \Omega$. Then $\exists z_0 \in D : z_0 \notin \Omega$. Since Ω is simply connected, there is a family of curves $(\gamma_t)_{t \in [0,1]}$, a continuous deformation of $\gamma : \gamma_0 = \gamma, \gamma_1 = z_1 \in \Omega$ and $\gamma_t \subset \Omega \forall t \in [0,1]$. Since $z_0 \neq z_1, \exists \varepsilon > 0 : z_0$ is in the exterior of $\gamma_{1-\varepsilon}$. By Intermediate value theorem, $\exists \tau \in [0,1] : z_0 \in \gamma_\tau \subset \Omega$, a contradiction.

So f is analytic in $D \cup \gamma$, and

$$\begin{aligned} \int_{\gamma} f \, dz &= \text{circ}_{\gamma}(\underline{f}) + i \, \text{flux}_{\gamma}(\underline{f}) \\ &= \int_D \nabla \times \underline{f} + i \int_D \nabla \cdot \underline{f} \quad \text{Green's on first term, Gauss's on second} \\ &= \int_D \left(-\frac{\partial v}{\partial x} - \frac{\partial u}{\partial y} \right) + i \int_D \left(\frac{\partial u}{\partial x} - \frac{\partial v}{\partial y} \right) \\ &= 0 + i \cdot 0 \quad \text{Cauchy-Riemann} \\ &= 0. \end{aligned}$$

□

- Remark.**
1. Analytic functions give rise to very special vector fields \underline{f} with both $\text{curl } \underline{f}$ and $\text{div } \underline{f}$ equal to zero.
 2. Consider $\int_{\partial \mathbb{B}_R(0)} z^{-1} \, dz$. z^{-1} is analytic in $\mathbb{C} \setminus \mathbb{B}_R(0) \forall R > 0$, which is not simply connected, in other words, we cannot deform a circle to a point since the hole won't let us. And indeed we know the integral is $2\pi i \neq 0$.

It turns out that Cauchy's theorem is a very powerful tool for computing contour integrals.

Theorem 4.6.9 (Contour deformation). $\Omega \subset \mathbb{C}$ positively oriented, regular such that $\partial\Omega = \gamma_1 \cup \gamma_2$ and $\gamma_1 \cap \gamma_2 = \emptyset$ and γ_i 's are contours. Let $f : \Omega \cup \gamma_1 \cup \gamma_2$ be analytic. Then

$$\int_{\gamma_1} f + \int_{\gamma_2} f = 0.$$

Equivalently,

$$\int_{\gamma_1} f = \int_{-\gamma_2} f.$$

(Deforming the contour within in the region of analyticity does not change the integral of an analytic function.)

Picturesque proof. Parameterise γ_i from p_i and η from p_2 to p_1 . Note that $\Omega \setminus \eta$ is simply connected. So by Cauchy's theorem,

$$\begin{aligned} \int_{\partial(\Omega \setminus \eta)} f &= \int_{\gamma_2} f + \int_{\eta} f + \int_{\gamma_1} f + \int_{-\eta} f \\ &= \int_{\gamma_1} f + \int_{\gamma_2} f \\ &= 0. \end{aligned}$$

□

Remark. 1. Terminology: given contour γ , $I(\gamma)$ denotes interior of γ which is open, bounded subset of \mathbb{C} and $\partial I(\gamma) = \gamma$, and $\overline{I(\gamma)} = I(\gamma) \cup \gamma$. $O(\gamma)$ denotes outside of γ , which is equal to $\overline{I(\gamma)}^C$.

2. We established before that

$$\int_{\partial \mathbb{B}_R(0)} z^n dz = 2\pi i \delta_{n,-1}.$$

Now similarly,

$$\int_{\partial \mathbb{B}_R(a)} (z - a)^n dz = 2\pi i \delta_{n,-1}.$$

Fix $z \in \mathbb{C}$,

$$\frac{1}{2\pi i} \int_{\gamma} \frac{1}{z - w} dw = \begin{cases} 0 & z \in O(\gamma) \\ 1 & z \in I(\gamma) \end{cases}$$

since if $z \in O(\gamma)$ it's just Cauchy's theorem, but if $z \in I(\gamma)$ we can surround z by a ball and deform γ to the ball continuously, and by previous theorem the two integrals are the same, so it's $\frac{2\pi i}{2\pi i} = 1$.

Theorem 4.6.10. Let $\gamma \subset \mathbb{C}$ be a contour (oriented counterclockwise). Suppose f is analytic in $\overline{I(\gamma)}$. Then $\forall z \in I(\gamma)$,

$$f(z) = \frac{1}{2\pi i} \int_{\gamma} \frac{f(w)}{w - z} dw,$$

i.e. given analytic function and its values on a contour, we can give value of the function anywhere inside the contour.

Proof. Note that $\frac{f(w)}{w-z}$ is analytic in $I(\gamma) \setminus \mathbb{B}_R(z)$ where $R > 0 : \mathbb{B}_R(z) \subset I(\gamma)$, so

$$\begin{aligned} \frac{1}{2\pi i} \int_{\gamma} \frac{f(w)}{w-z} dw &= \frac{1}{2\pi i} \int_{\partial \mathbb{B}_R(z)} \frac{f(w)}{w-z} dw \\ &= \frac{1}{2\pi i} \int_{\partial \mathbb{B}_R(z)} \frac{f(z)}{w-z} dw + \underbrace{\frac{1}{2\pi i} \int_{\partial \mathbb{B}_R(z)} \frac{f(w) - f(z)}{w-z} dw}_{\text{error term}} \\ &= f(z) + \frac{1}{2\pi i} \int_{\partial \mathbb{B}_R(z)} f'(z) + g_z(w) dw \end{aligned}$$

where $|g_z(w)| \rightarrow 0$ as $|w-z| \rightarrow 0$, and since R is arbitrarily small,

$$\begin{aligned} \left| \frac{1}{2\pi i} \int_{\partial \mathbb{B}_R(z)} f'(z) + g_z(w) dw \right| &= \frac{1}{2\pi} \int_{\partial \mathbb{B}_R(z)} |f'(z) + g_z(w)| |dw| \\ &\leq \frac{1}{2\pi} \left(|f'(z)| + \sup_{z \in \mathbb{B}_R(z)} |g_z(w)| \right) 2\pi R \\ &= 0 \end{aligned}$$

so the error term vanishes and we have what's desired.

□

We can generalise this statement.

Theorem 4.6.11. Let $\gamma \subset \mathbb{C}$ be a contour (oriented counterclockwise). Suppose f is analytic in $\overline{I(\gamma)}$. Then $\forall z \in I(\gamma), \forall n \in \mathbb{N}_0$,

$$f^{(n)}(z) = \frac{n!}{2\pi i} \int_{\gamma} \frac{f(w)}{(w-z)^{n+1}} dw,$$

i.e. the derivative of any order exists at any point where f is analytic and we can differentiate by integrating.

Shortcut proof. f is analytic at every $w \in \gamma$. Therefore $\exists \varepsilon(w) : f$ is analytic in $\mathbb{B}_{\varepsilon(w)}(w)$. Consider $\{\mathbb{B}_{\varepsilon(w)}(w)\}_{w \in \gamma}$, which is an open cover of γ , i.e. union of elements in this set is open

and contains γ . Note that γ is compact (closed, bounded), so by a theorem which will be proved in MA260, \exists a finite subcover $\{\mathbb{B}_{\varepsilon(w_i)}(w_i)\}_{i=1}^N$ of γ . Let $\tilde{\gamma}$ be a contour such that

$$\tilde{\gamma} \subset \left(\bigcup_{i=1}^N \mathbb{B}_{\varepsilon(w_i)}(w_i) \right) \cap O(\gamma).$$

The following picture makes clear. The thick curve is γ , where f is analytic, so we can exploit this fact and find an outside curve which is still in the ball-cover, and f is analytic in $\tilde{\gamma}$ and $I(\tilde{\gamma})$.

Then by previous theorem

$$f(z) = \frac{1}{2\pi i} \int_{\tilde{\gamma}} \frac{f(w)}{w-z} dw,$$

so

$$\begin{aligned} \frac{f(z+h) - f(z)}{h} &= \frac{1}{2h\pi i} \int_{\tilde{\gamma}} \frac{f(w)}{w-z-h} - \frac{f(w)}{w-z} dw \\ &= \frac{1}{2h\pi i} \int_{\tilde{\gamma}} \frac{f(w)h}{(w-z-h)(w-z)} dw \\ &= \frac{1}{2\pi i} \int_{\tilde{\gamma}} f(w) \frac{1}{(w-z)^2} dw + \frac{1}{2\pi i} E_h, \end{aligned}$$

where

$$\begin{aligned} E_h &= \int_{\tilde{\gamma}} f(w) \left(\frac{1}{(w-z-h)(w-z)} - \frac{1}{(w-z)^2} \right) dw \\ &= \int_{\tilde{\gamma}} f(w) \frac{h}{(w-z)^2(w-z-h)} dw \\ &= \text{for any } |h| < r \quad h \int_{\partial \mathbb{B}_{2R}(z)} \frac{f(w)}{(w-z)^2(w-z-h)} dw \end{aligned}$$

where the integrand is uniformly bounded as $|w-z-h| \geq r$.

Therefore as $h \rightarrow 0$, E_h vanishes. Hence

$$f'(z) = \frac{1}{2\pi i} \int_{\tilde{\gamma}} f(w) \frac{1}{(w-z)^2} dw.$$

Now, pick any $z \in I(\tilde{\gamma})$,

$$\begin{aligned} \frac{f'(z+h) - f'(z)}{h} &= \frac{1}{2h\pi i} \int_{\tilde{\gamma}} f(w) \left(\frac{1}{(w-z-h)^2} - \frac{1}{(w-z)^2} \right) dw \\ &= \frac{1}{2\pi i} \int_{\tilde{\gamma}} f(w) \frac{2(w-z) - h}{(w-z-h)^2(w-z)^2} dw \\ &= \frac{2}{2\pi i} \int_{\tilde{\gamma}} \frac{f(w)}{(w-z)^3} dw + E_h \end{aligned}$$

where we separate the integral to the target and error term E_h by putting $h = 0$. Then $E_h \rightarrow 0$ as $h \rightarrow 0$ similarly, so we have

$$f''(z) = \frac{2}{2\pi i} \int_{\tilde{\gamma}} \frac{f(w)}{(w-z)^3} dw,$$

as desired. We proceed by induction to get the general result: $f''(z)$ exists $\forall z \in I(\tilde{\gamma}) \Rightarrow f'$ is analytic in $I(\tilde{\gamma}) \Rightarrow f'$ is analytic in $\overline{I(\gamma)}$. So we've proven that

$$f \text{ analytic in } \overline{I(\gamma)} \Rightarrow f' \text{ analytic in } \overline{I(\gamma)}.$$

Therefore $f^{(n)}$ is analytic in $\overline{I(\gamma)}$. So by Theorem 4.6.10,

$$\begin{aligned} f^{(n)}(z) &= \frac{1}{2\pi i} \int_{\gamma} \frac{f^{(n)}(w)}{w-z} dw \\ &= \frac{1}{2\pi i} \left(- \int_{\gamma} f^{(n-1)}(w) \frac{\partial}{\partial w} \frac{1}{w-z} dw \right) \quad \text{integration by parts} \\ &= \frac{1}{2\pi i} \int_{\gamma} f^{(n-1)}(w) \frac{1}{(w-z)^2} dw \\ &= \frac{2}{2\pi i} \int_{\gamma} f^{(n-2)}(w) \frac{1}{(w-z)^3} dw \quad \text{integration by parts again} \\ &= \dots \quad \text{again and again} \\ &= \frac{n!}{2\pi i} \int_{\gamma} f(w) \frac{1}{(w-z)^{n+1}} dw, \end{aligned}$$

as desired. □

4.6.2 Consequences of Cauchy's theorem

Theorem 4.6.12 (Taylor's theorem). Let f be analytic in $\mathbb{B}_R(a) \subset \mathbb{C}$, $R > 0$, $a \in \mathbb{C}$. Then $\exists! (c_n)_{n \geq 0} \subset \mathbb{C} : \forall z \in \mathbb{B}_R(a)$,

$$f(z) = \sum_{n=0}^{\infty} c_n (z-a)^n,$$

moreover,

$$c_n = \frac{1}{2\pi i} \int_{\gamma} \frac{f(w)}{(w-z)^{n+1}} dw = \frac{f^{(n)}(a)}{n!}$$

where $\gamma \subset \mathbb{B}_R(a)$ is any contour such that $a \in I(\gamma)$.

(Informally, if f is analytic at a then its Taylor series has a positive radius of convergence and is equal to f within the corresponding ball.)

Proof. We know $\forall z \in \mathbb{B}_R(a)$, $\exists \gamma \in (|z-a|, R) : \mathbb{B}_r(a) \subset \mathbb{B}_R(a)$.

Since f is analytic in $\overline{\mathbb{B}_r(a)}$, by Theorem 4.6.10 we have

$$\begin{aligned} f(z) &= \frac{1}{2\pi i} \int_{\partial \mathbb{B}_r(a)} \frac{f(w)}{w-z} dw \\ &= \frac{1}{2\pi i} \int_{\partial \mathbb{B}_r(a)} \frac{f(w)}{w-a} \frac{w-a}{w-z} dw \\ &= \frac{1}{2\pi i} \int_{\partial \mathbb{B}_r(a)} \frac{f(w)}{w-a} \frac{1}{1 - \frac{z-a}{w-a}} dw. \end{aligned}$$

Note that

$$\left| \frac{z-a}{w-a} \right| = \frac{|z-a|}{r} < 1.$$

So

$$\frac{1}{1 - \frac{z-a}{w-a}} = \sum_{n=0}^{\infty} \left(\frac{z-a}{w-a} \right)^n$$

which converges uniformly with respect to w by the M -test. This means we can interchange integration and summation and we have

$$\begin{aligned} f(z) &= \frac{1}{2\pi i} \int_{\partial \mathbb{B}_r(a)} \frac{f(w)}{w-a} \sum_{n=0}^{\infty} \left(\frac{z-a}{w-a} \right)^n dw \\ &= \frac{1}{2\pi i} \sum_{n=0}^{\infty} \int_{\partial \mathbb{B}_r(a)} \frac{f(w)}{(w-a)(w-a)^n} dw (z-a)^n. \end{aligned}$$

By Theorem 4.6.11 this is what's desired. $\partial \mathbb{B}_r(a)$ can be replaced with any γ encompassing a by Contour deformation theorem ($\gamma \subset \mathbb{B}_R(a)$).

For uniqueness, suppose

$$f(z) = \sum_{n=0}^{\infty} b_n (z-a)^n \quad \forall z \in \mathbb{B}_\rho(a) \text{ for some } \rho > 0 \quad (*)$$

then the right hand side of (*) converges uniformly in $\overline{\mathbb{B}_{\rho'}(a)} \forall \rho' < \rho$. So we can differentiate term by term for any $z \in \mathbb{B}_{\rho'}(a)$. By Theorem 3.3.4, $b_n = \frac{1}{n!} f^{(n)}(a) = c_n$. \square

Example 4.6.13. Let $f : z \mapsto (1+z)^a$ in $\mathbb{B}_1(0)$ and $a \in \mathbb{C}$ fixed. We know $f(z) = e^{a \operatorname{Log}(1+z)}$ is analytic in $\mathbb{B}_1(0)$ since $z \mapsto e^z$ is entire and $\operatorname{Log}(1+z)$ is analytic in $\mathbb{C} \setminus \{x \leq -1\}$. So for any $\rho < 1$,

$$(1+z)^a = \sum_{n=0}^{\infty} z^n \frac{1}{2\pi i} \int_{\partial \mathbb{B}_{\rho}(0)} \frac{(1+w)^a}{w^{n+1}} dw.$$

If we denote $\frac{1}{2\pi i} \int_{\partial \mathbb{B}_{\rho}(0)} \frac{(1+w)^a}{w^{n+1}} dw$ by c_n we have

$$\begin{aligned} c_n &= \frac{1}{2\pi i} \frac{1}{-n} \int (w^{-n})' (1+w)^a dw \\ &= \frac{1}{2\pi i} \frac{1}{n!} \int w^{-n} a (1+w)^{a-1} dw \quad \text{integration by parts} \\ &= \frac{1}{2\pi i} \frac{a}{n} \int_{\partial \mathbb{B}_{\rho}(0)} w^{-n} (1+w)^{a-1} dw \\ &= \frac{1}{2\pi i} \frac{a(a-1)}{n(n-1)} \int_{\partial \mathbb{B}_{\rho}(0)} w^{-(n-1)} (1+w)^{a-2} dw \quad \text{by parts again} \\ &= \frac{1}{2\pi i} \prod_{k=0}^{n-1} \frac{a-k}{n-k} \int \frac{(1+w)^{a-n}}{w} dw \\ &= \prod_{k=0}^{n-1} \frac{a-k}{n-k} \int \frac{(1+w)^{a-n}}{w} \frac{dw}{2\pi i}. \end{aligned}$$

We know $w \mapsto (1+w)^{a+n}$ is analytic at $w = 0$. So

$$\frac{(1+w)^{a-n} - 1^{a-n}}{w} = ((1+z)^{a-n})'|_{z=0} + \varphi(w)$$

where the error term $\varphi(w) \rightarrow 0$ as $w \rightarrow 0$. So

$$\frac{1}{2\pi i} \int_{\partial \mathbb{B}_{\rho}(0)} \frac{(1+w)^{a-n}}{w} dw = \underbrace{\frac{1}{2\pi i} \int \frac{1}{w} dw}_1 + \underbrace{\frac{1}{2\pi i} \int_{\partial \mathbb{B}_{\rho}(0)} (a-n) + \varphi(w) dw}_0,$$

therefore

$$c_n = \prod_{k=0}^{n-1} \frac{a-k}{n-k} = \frac{1}{n!} \prod_{k=0}^{n-1} (a-k).$$

By above theorem, $\sum_{n=0}^{\infty} c_n z^n$ converges for any $|z| \leq \rho$ where $\rho \in (0, 1)$, so radius of convergence $R \geq 1$.

Theorem 4.6.14 (Liouville's theorem). Let $f : \mathbb{C} \rightarrow \mathbb{C}$ be entire. If f is bounded, then f is constant.

Proof. f is bounded, meaning $\exists M > 0 : |f(z)| \leq M \forall z \in \mathbb{C}$. For any $z \in \mathbb{C}$, take $R > |z|$,

then

$$f(0) = \frac{1}{2\pi i} \int_{\partial \mathbb{B}_R(0)} \frac{f(w)}{w} dw$$

and

$$f(z) = \frac{1}{2\pi i} \int_{\partial \mathbb{B}_R(0)} \frac{f(w)}{w - z} dw.$$

To see f is constant we need $f(z) - f(0) = 0$. Indeed:

$$\begin{aligned} |f(z) - f(0)| &= \left| \frac{1}{2\pi i} \int_{\partial \mathbb{B}_R(0)} f(w) \left(\frac{1}{w - z} - \frac{1}{w} \right) dw \right| \\ &= \frac{|z|}{2\pi} \left| \int_{\partial \mathbb{B}_R(0)} f(w) \frac{1}{(w - z)w} dw \right| \\ &\leq \frac{|z|}{2\pi} \int_{\partial \mathbb{B}_R(0)} \frac{|f(w)|}{|w||w - z|} |dw| \\ &\leq \frac{|z|}{2\pi} \int_{\partial \mathbb{B}_R(0)} \frac{M}{R(R - |z|)} |dw| \\ &= \frac{|z|}{2\pi} \frac{M}{R(R - |z|)} 2\pi R \\ &= \frac{|z|M}{R - |z|} \end{aligned}$$

but since f is entire, we can have R as large as we want. Therefore $\frac{|z|M}{R - |z|} \rightarrow 0$ and therefore $f(z) = f(0)$. \square

Theorem 4.6.15 (Fundamental theorem of algebra). Let $p : \mathbb{C} \rightarrow \mathbb{C}$ a non-constant polynomial. Then $\exists a \in \mathbb{C} : p(a) = 0$. (Any complex non-constant polynomial has a root.)

Proof by contradiction. Suppose $p(z) \neq 0 \forall z \in \mathbb{C}$. Then $f := \frac{1}{p}$ is analytic in \mathbb{C} , i.e. entire. Indeed, $z \mapsto p(z)$ is entire and $x \mapsto \frac{1}{x}$ is analytic when $x \neq 0$. Since p is non-constant, $\exists n > 0 : p(z) = \sum_{k=0}^n c_k z^k$ where $c_n \neq 0$. So $|p(z)| \rightarrow \infty$ as $|z| \rightarrow \infty$. Then $\exists R > 0 : |p(z)| \geq 1 \forall |z| \geq R$. So $|f(z)| \leq 1 \forall |z| \geq R$. But for $|z| \leq R$, f is also bounded, as an analytic hence continuous function on a closed bounded set. We conclude that f is entire and bounded, so constant, hence p is constant which is a contradiction. \square

Theorem 4.6.16. $f_n : \Omega \rightarrow \mathbb{C}$, Ω open, $n \geq 1$ are all analytic in Ω . If $f_n \rightrightarrows f : \Omega \rightarrow \mathbb{C}$, then f is analytic.

Proof. $\forall z \in \Omega$, let $r > 0$, pick small enough $\overline{\mathbb{B}_r(z)} \subset \Omega$. Since f_n is analytic,

$$f_n(z) = \frac{1}{2\pi i} \int_{\partial \mathbb{B}_r(z)} \frac{f_n(w)}{w - z} dw$$

so

$$\begin{aligned} f(z) &= \frac{1}{2\pi i} \lim_{n \rightarrow \infty} \int_{\partial \mathbb{B}_r(z)} \frac{f_n(w)}{w - z} dw \\ &= \frac{1}{2\pi i} \int_{\partial \mathbb{B}_r(z)} \frac{f(w)}{w - z} dw + \lim_{n \rightarrow \infty} E_n(z) \end{aligned}$$

where $E_n(z)$ is the error term (difference of the two). We know that by uniform convergence, $\forall \varepsilon > 0$, $\exists N_\varepsilon : \forall n > N_\varepsilon$, $\sup_{\Omega} |f - f_n| < \varepsilon$, so

$$\begin{aligned} |E_n(z)| &\leq \frac{1}{2\pi} \int_{\partial \mathbb{B}_r(z)} \frac{|f_n(w) - f(w)|}{|w - z|} |dw| \\ &< \frac{1}{2\pi r} \varepsilon \int_{\partial \mathbb{B}_r(z)} 1 |dw| \\ &= \frac{1}{2\pi r} \varepsilon 2\pi r = \varepsilon, \end{aligned}$$

so $\lim_{n \rightarrow \infty} E_n(z) = 0$, i.e.

$$f(z) = \frac{1}{2\pi i} \int_{\partial \mathbb{B}_r(z)} \frac{f(w)}{w - z} dw.$$

Note that $f_n|_{\partial \mathbb{B}_r(z)} \rightrightarrows f|_{\partial \mathbb{B}_r(z)}$, so $f|_{\partial \mathbb{B}_r(z)}$ is continuous (on a closed bounded set), hence bounded. From the proof of Theorem 4.6.11 we know that f' exists at every point $z \in \Omega$, i.e. f is analytic. \square

4.6.3 Calculation of integrals over \mathbb{R} using Cauchy's theorem

Definition 4.6.17. Let f be defined on a subset of \mathbb{C} . f has a *pole* of order $m \in \mathbb{N}$ at $a \in \mathbb{C}$ if \exists a neighbourhood U of $a : \forall z \in U \setminus \{a\}$,

$$f(z) = \frac{c_{-m}}{(z - a)^m} + \frac{c_{-m+1}}{(z - a)^{m-1}} + \cdots + \frac{c_{-1}}{z - a} + \phi(z)$$

where ϕ is analytic in U , $c_i \in \mathbb{C}$ are constants. Moreover, c_{-1} is called the *residue* of f at a , $c_{-1} = \text{Res } f(a)$. $c_{-m} \neq 0$.

Having a pole means the function is not defined at a certain point but on a neighbourhood of it, and we know that as we approach the point the function blows up at a rate quantified by the pole's order m and described as a Laurent polynomial of the distance.

Example 4.6.18. Let $f : z \mapsto \frac{1}{z^2 + a^2}$, $a > 0$. We claim f has first order poles at $z = \pm ia$. Indeed,

$$f(z) = \frac{1}{2ia} \left(\frac{1}{z - ia} - \frac{1}{z + ia} \right)$$

and we can read off the pole $z = ia$, corresponding $\phi(z) = -\frac{1}{z + ia}$ and $\text{Res } f = \frac{1}{2ia}$ from the above and the definition. Similar (in fact symmetrically) for the other pole $z = -ia$.

Theorem 4.6.19 (Residue theorem). Let $\gamma \subset \Omega$ be a contour oriented counterclockwise. Suppose f is analytic in $\bar{I}(\gamma) \setminus \{z_1, \dots, z_n\}$ where z_i 's are finitely many points living inside $I(\gamma)$. Moreover, suppose f has poles at z_1, \dots, z_n . Then

$$\int_{\gamma} f(z) \, dz = \sum_{k=1}^n 2\pi i \operatorname{Res} f(z_k).$$

Proof. Choose $r > 0$ such that $f(z) = \sum_{k=1}^m c_k (z - z_1)^k + \phi_1(z)$ is analytic in $\overline{\partial \mathbb{B}_r(z)}$.

By contour deformation theorem,

$$\begin{aligned} \int_{\gamma} f &= \int_{\tilde{\gamma} \cup \eta \cup \partial \mathbb{B}_r(z_1) \cup (-\eta)} f = \int_{\tilde{\gamma}} f + \int_{\eta} f + \int_{\partial \mathbb{B}_r(z_1)} f + \int_{-\eta} f \\ &= \int_{\tilde{\gamma}} f + \int_{\partial \mathbb{B}_r(z_1)} f \end{aligned} \quad (*)$$

where

$$\begin{aligned} \int_{\partial \mathbb{B}_r(z_1)} f &= \sum_{k=1}^{-m} c_k \underbrace{\int_{\partial \mathbb{B}_r(z_1)} (z - z_1)^k \, dz}_{2\pi i \delta_{k,-1} \text{ by Remark before Theorem 4.6.10}} + \underbrace{\int_{\partial \mathbb{B}_r(z_1)} \phi_1 \, dz}_0 \text{ by Cauchy} \\ &= 2\pi i c_{-1} = 2\pi i \operatorname{Res} f(z_1). \end{aligned}$$

Now perform induction on $\tilde{\gamma}$ we have what's desired. \square

Example 4.6.20. Calculate

$$I = \int_{-\infty}^{\infty} \frac{1}{x^2 + a^2} \, dx$$

which is improper and absolutely convergent. We know this before introduction of complex analysis and we do this by computing

$$\lim_{R \rightarrow \infty} \int_{-R}^R \frac{1}{x^2 + a^2} \, dx.$$

FTC: Let $x = ay$, then

$$I = \lim_{R \rightarrow \infty} \frac{1}{a} \int_{-\frac{R}{a}}^{\frac{R}{a}} \frac{1}{x^2 + 1} \, dx = \lim_{R \rightarrow \infty} \frac{1}{a} \arctan(x) \Big|_{-\frac{R}{a}}^{\frac{R}{a}} = \frac{1}{a} \left(\frac{\pi}{2} - \left(-\frac{\pi}{2} \right) \right) = \frac{\pi}{a}.$$

Contour integrals: Let $C_1^{(R)}$ be parameterised by $c_1(x) = x$, $x \in [-R, R]$ and $C_2^{(R)}$ by $c_2(x) = Re^{it}$, $x \in [0, \pi]$, and $\gamma_R := C_1 \cup C_2$.

Then

$$\begin{aligned}
 I &= \lim_{R \rightarrow \infty} \int_{C_1^{(R)}} \frac{1}{z^2 + a^2} dz \\
 &= \lim_{R \rightarrow \infty} \int_{C_1^{(R)}} \frac{1}{z^2 + a^2} dz + \underbrace{\int_{C_2^{(R)}} \frac{1}{z^2 + a^2} dz}_{\downarrow 0} \\
 &= \lim_{R \rightarrow \infty} \int_{\gamma} \frac{1}{z^2 + a^2} dz \\
 &= \lim_{R \rightarrow \infty} 2\pi i \frac{1}{2ia} = \frac{\pi}{a}.
 \end{aligned}$$

(Sanity check: as $R \rightarrow \infty$,

$$\left| \int_{C_2^{(R)}} \frac{1}{z^2 + a^2} dz \right| \leq \int_{C_2^{(R)}} \underbrace{\frac{1}{|z^2 + a^2|}}_{\approx R^2} \underbrace{|dz|}_{R dt} \leq 2 \int \frac{1}{R^2} R dt \rightarrow 0.$$

Lemma 4.6.21. $f, g : U \rightarrow \mathbb{C}$ analytic, U open. Let $a \in U : g(a) = 0$, $g'(a) \neq 0$ and $g(z) \neq 0 \forall z \neq a$. Then $\frac{f}{g} : U \setminus \{a\} \rightarrow \mathbb{C}$ has a first order pole. Moreover, $\text{Res } \frac{f}{g}(a) = \frac{f(a)}{g'(a)}$.

Proof. Analyticity means $\exists R_1 > 0 : \forall z \in \mathbb{B}_{R_1}(a) \subset U$,

$$g(z) = \sum_{n=1}^{\infty} g_n(z-a)^n \underset{g_1=g'(a) \neq 0}{=} g_1(z-a) \underbrace{\sum_{m=1}^{\infty} \frac{g_m}{g_1}(z-a)^m}_{h(z)},$$

and f, h are analytic in $\mathbb{B}_{R_1}(a)$. Also $h(a) = 1$, so $\exists R_2 \in (0, R_1] : h \neq 0$ in $\mathbb{B}_{R_2}(a)$, so that $\frac{f}{h}$ is analytic in $\mathbb{B}_{R_2}(a)$. Hence $\forall z \in \mathbb{B}_{R_2}(a) \setminus \{a\}$,

$$\begin{aligned}
 \frac{f(z)}{g(z)} &= \frac{f(z)}{g_1(z-a)h(z)} \\
 &= \frac{1}{g_1(z-a)} \left(\frac{f(a)}{h(a)} + (z-a)\phi(z) \right) \\
 &= \frac{f(a)}{g'(a)} \left(\frac{1}{z-a} + \phi(z) \right),
 \end{aligned}$$

which gives what's desired. □

Example 4.6.22. We have

$$I(k) = \int_{\mathbb{R}} \frac{e^{ikx}}{x^2 + a^2} dx, \quad a > 0, k \in \mathbb{R}.$$

Note that

$$\left| \frac{e^{ikx}}{x^2 + a^2} \right| \leq \frac{1}{x^2},$$

so it converges absolutely. Hence, using the same $C_i^{(R)}$ and γ_R notation,

$$\begin{aligned} I(k) &= \lim_{R \rightarrow \infty} \int_{-R}^R \frac{e^{ikx}}{x^2 + a^2} dx \\ &= \lim_{R \rightarrow \infty} \int_{C_1^{(R)}} \frac{e^{ikz}}{z^2 + a^2} dz \end{aligned}$$

Now we know that $\frac{1}{z^2 + a^2}$ goes to 0 fast enough to ensure convergence, but what about the exponential on the numerator? Note that as $z \rightarrow \infty$ along the imaginary axis, $e^{ikz} \rightarrow 0$ but as it $\rightarrow -\infty$, $e^{ikz} \rightarrow \infty$, i.e. we only have a chance of convergence if we enclose the curve in the upper half of plane (like we did in the first such example). So

$$\begin{aligned} &= \lim_{R \rightarrow \infty} \int_{C_1^{(R)}} \frac{e^{ikz}}{z^2 + a^2} dz + \int_{C_2^{(R)}} \frac{e^{ikz}}{z^2 + a^2} dz \\ &= \lim_{R \rightarrow \infty} \int_{\gamma_R} \frac{e^{ikz}}{z^2 + a^2} dz \end{aligned}$$

Let $f(z) = e^{ikz}$, $g(z) = z^2 + a^2$, then $g(ia) = 0$, $g(z) \neq 0 \forall z \neq ia$, $g'(z) = 2z \neq 0$. So using the lemma we know that $\frac{e^{ikz}}{z^2 + a^2}$ has a first order pole at $z = ia$ and $\text{Res} = \frac{f(ia)}{g'(ia)} = \frac{e^{-ka}}{2ia}$. By Residue theorem we then have

$$= 2\pi i \frac{e^{-ka}}{2ia} = \frac{\pi e^{-ka}}{a}, \quad k \geq 0.$$

For $k < 0$, we use lower half of plane and it's symmetric, i.e. $k \mapsto I(k)$ is even (can see this by change of variables).

We conclude that

$$I(k) = \frac{\pi e^{-|k|a}}{a}, \quad \forall k \in \mathbb{R}.$$

(Sanity check: as $R \rightarrow \infty$,

$$\begin{aligned} \left| \int_{C_2^{(R)}} \frac{e^{ikz}}{z^2 + a^2} dz \right| &\leq \int_0^\pi \frac{|e^{ikRe^{it}}|}{|z^2 + a^2|} R dt \\ &\stackrel{R \text{ sufficiently large}}{\leq} \frac{2R}{R^2} \int_0^\pi |e^{ikR(\cos t + i \sin t)}| dt \\ &= \frac{2}{R} \int_0^\pi |e^{ikR \cos t}| |e^{-kR \sin t}| dt \\ &= \frac{2}{R} \int_0^\pi |e^{-kR \sin t}| dt \leq \frac{2}{R} \rightarrow 0. \end{aligned}$$

See notes for a (similar) proof of

$$I(k) = \int_{\mathbb{R}} \frac{e^{ikx}}{\cosh x} \, dx = \frac{\pi}{\cosh \frac{k\pi}{2}}, \quad k \in \mathbb{R}.$$
